PP LANGUAGE: UNIT COVERED-1,2,3,4,5, **

**Some more topics are also covered which are beyond the syllabus.

PYTHON PROGRAMMING LANGUAGE

FALL SEMESTER, YEAR (4th, 2nd)

FALL SESSION (2021-22)

(PP LANGUAGE)
MS. SHWETA TIWARI
Published: APRIL, 2022

Language Fundamentals

Introduction

- **Python is a general purpose high level programming language.**

- **Python was developed by Guido Van Rossam in 1989 while working at NationalResearch Institute at Netherlands.**

- **But officially Python was made available to public in 1991. The official Date of Birth forPython is : Feb 20th 1991.**

- **Python is recommended as first programming language for beginners.**

Eg1: To print

Helloworld:Java:

```java
1)  public class HelloWorld
2)  {
3)    p s v main(String[] args)
4)    {
5)      SOP("Hello world");
6)    }
7)  }
```

C:

```c
1) #include<stdio.h>
2) void main()
3) {
4)   print("Hello world");
5) }
```

Python:

print("Hello World")

Eg2: To print the sum of 2

numbers**Java:**

```java
1) public class Add
2) {
3)    public static void main(String[] args)
4)    {
5)       int a,b;
6)       a =10;
7)       b=20;
8)       System.out.println("The Sum:"+(a+b));
9)    }
10) }
```

C:

```c
1) #include <stdio.h>
2)
3) void main()
4) {
5)    int a,b;
6)    a =10;
7)    b=20;
8)    printf("The Sum:%d",(a+b));
9) }
```

Python:

```python
1) a=10
2) b=20
3) print("The Sum:",(a+b))
```

The name Python was selected from the TV
Shows"The Complete
Monty
Python'
s
Circus", which was broadcasted in BBC from 1969 to 1974.

Guido developed Python language by taking almost all programming features
fromdifferent languages

1. Functional Programming Features from C
2. Object Oriented Programming Features from C++
3. Scripting Language Features from Perl and Shell Script

4. Modular Programming Features from Modula-3

Most of syntax in Python Derived from C and ABC

languages.<u>Where we can use Python:</u>

We can use everywhere. The most common important application areas are

1. For developing Desktop Applications
2. For developing web Applications
3. For developing database Applications
4. For Network Programming
5. For developing games
6. For Data Analysis Applications
7. For Machine Learning
8. For developing Artificial Intelligence Applications
9. For IOT
...

<u>Note:</u>

Internally Google and Youtube use Python coding
NASA and Nework Stock Exchange Applications developed by Python.
Top Software companies like Google, Microsoft, IBM, Yahoo using Python.

<u>Features of Python:</u>

<u>1.</u> <u>Simple and easy to learn:</u>

Python is a simple programming language. When we read Python program,we can feel likereading english statements.
The syntaxes are very simple and only 30+ kerywords are available.
When compared with other languages, we can write programs with very less number oflines. Hence more readability and simplicity.
We can reduce development and cost of the project.

<u>2.</u> <u>Freeware and Open Source:</u>

We can use Python software without any licence and it is freeware.

Its source code is open,so that we can we can customize based on our

requirement.<u>Eg:</u> Jython is customized version of Python to work with Java

Applications.

3. High Level Programming language:

Python is high level programming language and hence it is programmer friendly language.Being a programmer we are not required to concentrate low level activities like memory management and security etc..

4. Platform Independent:

Once we write a Python program, it can run on any platform without rewriting once again. Internally PVM is responsible to convert into machine understandable form.

5. Portability:

Python programs are portable. i.e., we can migrate from one platform to another platformvery easily. Python programs will provide same results on any platform.

6. Dynamically Typed:

In Python we are not required to declare type for variables. Whenever we are assigning the value, based on value, type will be allocated automatically. Hence Python is consideredas dynamically typed language.

But Java, C etc. are Statically Typed Languages b'z we have to provide type at the beginningonly.

This dynamic typing nature will provide more flexibility to the programmer.

7. Both Procedure Oriented and Object Oriented:

Python language supports both Procedure oriented (like C, pascal etc.) and object oriented(like C++, Java) features. Hence, we can get benefits of both like security and reusability etc

8. Interpreted:

We are not required to compile Python programs explicitly. Internally Python interpreterwill take care that compilation.

If compilation fails interpreter raised syntax errors. Once compilation success then PVM (Python Virtual Machine) is responsible to execute.

9. Extensible:

We can use other language programs in
Python.The main advantages of this approach
are:

1. We can use already existing legacy non-Python code
2. We can improve performance of the application

10. Embedded:

We can use Python programs in any other language programs.
i.e., we can embed Python programs anywhere.

11. Extensive Library:

Python has a rich inbuilt library.
Being a programmer, we can use this library directly and we are not responsible
toimplement the functionality.

etc...

Limitations of Python:

1. Performance wise not up to the mark b'z it is interpreted language.
2. Not using for mobile Applications

Flavors of Python:

1. CPython:
It is the standard flavor of Python. It can be used to work with C language Applications

2. Jython or JPython:
It is for Java Applications. It can run on JVM

3. IronPython:
It is for C#.Net platform

4. PyPy:
The main advantage of PyPy is performance will be improved because JIT compiler is
available inside PVM.

5. RubyPython
 For Ruby Platforms

6. AnacondaPython
It is specially designed for handling large volume of data processing.
...

<u>Python Versions:</u>

Python 1.0V introduced in Jan 1994
Python 2.0V introduced in October 2000
Python 3.0V introduced in December
2008

<u>Note:</u> Python 3 won't provide backward compatibility to Python2
i.e there is no guarantee that Python2 programs will run in Python3.

Current versions

Python 3.6.1   **Python 2.7.13**

Identifiers

A name in Python program is called identifier.
It can be class name or function name or module name or variable

name.a = 10

Rules to define identifiers in Python:

1. The only allowed characters in Python are

- **alphabet symbols (either lower case or upper case)**
- **digits (0 to 9)**
- **underscore symbol (_)**

  By mistake if we are using any other symbol like $ then we will get syntax error.

- **cash = 10 √**
- **ca$h =20 □**

 2. Identifier should not start with digit

- **123total □**
- **total123 √**

 3. Identifiers are case sensitive. Of course, Python language is case sensitive language.

- **total=10**
- **TOTAL=999**
- **print(total) #10**
- **print(TOTAL) #999**

Identifier:

1. Alphabet Symbols (Either Upper case OR Lower case)

2. If Identifier is start with Underscore (_) then it indicates it is private.

3. Identifier should not start with Digits.

4. Identifiers are case sensitive.

5. We cannot use reserved words as identifiers **E.g.:** def=10 ☐

6. There is no length limit for Python identifiers. But not recommended to use too lengthyidentifiers.

7. Dollor ($) Symbol is not allowed in Python.

Q. Which of the following are valid Python identifiers?

1) 123total ☐
2) total123 √
3) java2share √
4) ca$h ☐
5) _abc_abc_ √
6) def ☐
7) if ☐

Note:

1. If identifier starts with _ symbol then it indicates that it is private
2. If identifier starts with __(two underscore symbols) indicating that strongly privateidentifier.
3.If the identifier starts and ends with two underscore symbols then the identifier islanguage defined special name, which is also known as magic methods.

Eg:__add__

Reserved Words

In Python some words are reserved to represent some meaning or functionality. Such typeof words is called Reserved words.

There are 33 reserved words available in Python.

- **True,False,None**
- **and, or ,not,is**
- **if,elif,else**
- **while,for,break,continue,return,in,yield**
- **try,except,finally,raise,assert**
- **import,from,as,class,def,pass,global,nonlocal,lambda,del,with**

Note:
1. All Reserved words in Python contain only alphabet symbols.

2. Except the following 3 reserved words, all contain only lower-case alphabet symbols.

- **True**
- **False**
- **None**

Eg: a= true □
    a=True √

>>> import keyword
>>> keyword.kwlist
['False', 'None', 'True', 'and', 'as', 'assert', 'break', 'class', 'continue', 'def', 'del', 'elif', 'else',
'except', 'finally', 'for', 'from', 'global', 'if', 'import', 'in', 'is', 'lambda', 'nonlocal', 'not',
**'or', 'pass', 'raise', 'return', 'try', 'while', 'with', 'yield']**

Data Types

Data Type represent the type of data present inside a variable.
In Python we are not required to specify the type explicitly. Based on value provided, the type will be assigned automatically. Hence Python is Dynamically Typed Language.

Python contains the following inbuilt data types
1. int
2. float
3.complex
4.bool
5.str
6.bytes
7.bytearray
8. range
9. list
10.tuple
11.set
12.frozenset
13.dict
14.None
Note: Python contains several inbuilt

functions**1.type()**
   to check the type of variable

2. id()
  to get address of object

3. print()
  to print the value

In Python everything is object

int data type:

We can use int data type to represent whole numbers (integral values)Eg:
  a=10
  type(a) #int

Note:
In Python2 we have long data type to represent very large integral values.
But in Python3 there is no long type explicitly and we can represent long values also byusing int type only.

We can represent int values in the following ways

1. Decimal form
2. Binary form
3. Octal form
4. Hexa decimal form

1. Decimal form(base-10):

It is the default number system in PythonThe allowed digits are: 0 to 9
Eg: a =10

2. Binary form(Base-2):

The allowed digits are : 0 & 1
Literal value should be prefixed with 0b or 0B

  Eg: a =
  0B1111a
  =0B123
  a=b111

3. Octal Form(Base-8):

The allowed digits are : 0 to 7
Literal value should be prefixed with 0o or 0O.

Eg: **a=0o123**
      a=0o786

4. Hexa Decimal Form(Base-16):

The allowed digits are : 0 to 9, a-f (both lower and upper cases are allowed)
Literal value should be prefixed with 0x or 0X

Eg:
  a =0XFACE
  a=0XBeef
  a
  =0XBeer

Note: **Being a programmer we can specify literal values in decimal, binary, octal and hexadecimal forms. But PVM will always provide values only in decimal form.**

a=10
b=0o10
c=0X1
0
d=0B1
0
print(a)1
0
print(b)8
print(c)1
6
print(d)2

Base Conversions

Python provide the following in-built functions for base conversions

1.bin():

We can use bin() to convert from any base to

binaryEg:

```
1)    >>> bin(15)
2) '0b1111'
3) >>> bin(0o11)
4) '0b1001'
5) >>> bin(0X10)
6) '0b10000'
```

2. oct():

We can use oct() to convert from any base to octal

Eg:

```
1)  >>> oct(10)
2)  '0o12'
3)  >>> oct(0B1111)
4)  '0o17'
5)  >>> oct(0X123)
6)  '0o443'
```

3. hex():

We can use hex() to convert from any base to hexa decimal

Eg:

```
1)  >>> hex(100)
2)  '0x64'
3)  >>> hex(0B111111)
4)  '0x3f'
5)  >>> hex(0o12345)
6)  '0x14e5'
```

float data type:

We can use float data type to represent floating point values (decimal values)

Eg: f=1.234
    type(f) float

We can also represent floating point values by using exponential form (scientific notation)

Eg: f=1.2e3
    print(f) 1200.0
instead of 'e' we can use 'E'

The main advantage of exponential form is we can represent big values in less memory.

***Note:**
 We can represent int values in decimal, binary, octal and hexa decimal forms. But we canrepresent float values only by using decimal form.

**Eg:**

```
1)    >>> f=0B11.01
2)  File "<stdin>", line 1
3)    f=0B11.01
```

```
4)          ^
5)  SyntaxError: invalid syntax
6)
7)  >>> f=0o123.456
8)    SyntaxError: invalid syntax
9)
10) >>> f=0X123.456
11)  SyntaxError: invalid syntax
```

Complex Data Type:

A complex number is of the form

a and b contain integers or floating point values

Eg:
  3+5j
  10+5.5j
  0.5+0.1j

In the real part if we use int value then we can specify that either by decimal,octal,binaryor hexa decimal form.
But imaginary part should be specified only by using decimal form.

```
1)  >>> a=0B11+5j
2)  >>> a
3)  (3+5j)
4)  >>> a=3+0B11j
5)    SyntaxError: invalid syntax
```

Even we can perform operations on complex type values.

```
1)  >>> a=10+1.5j
2)  >>> b=20+2.5j
3)  >>> c=a+b
4)  >>> print(c)
5)  (30+4j)
6)  >>> type(c)
7)  <class 'complex'>
```

Note: Complex data type has some inbuilt attributes to retrieve the real part and imaginary part

c=10.5+3.6j

c.real==>10.
5
c.imag==>3.
6

We can use complex type generally in scientific Applications and electrical engineeringApplications.

4.bool data type:

We can use this data type to represent Boolean values.
The only allowed values for this data type are:
True and False

Internally Python represents True as 1 and False as 0

b=True
type(b) =>bool

Eg:
a=10
b=20
c=a<b
print(c)==>Tr
ue

True+True==
>2True-
False==>1

str type:

str represents String data type.

A String is a sequence of characters enclosed within single quotes or double

quotes.s1='durga'
s1="durga"

By using single quotes or double quotes we cannot represent multi line string literals.

s1="durga

soft"

For this requirement we should go for triple single quotes(''') or triple double quotes(""")

s1='''durga
    soft'''

s1="""durga
    soft"""

 We can also use triple quotes to use single quote or double quote in our

 String.''' This is " character'''
 ' This i " Character '
 We can embed one string in another string

 '''This "Python class very helpful" for java students'''

Slicing of Strings:

slice means a piece
[ ] operator is called slice operator, which can be used to retrieve parts of
String.In Python Strings follows zero based index.
The index can be either +ve or -ve.
+ve index means forward direction from Left to Right
-ve index means backward direction from Right to Left

-5	-4	-3	-2	-1
d	u	r	g	a
0	1	2	3	4

```
1) >>> s="durga"
2) >>> s[0]
3) 'd'
4) >>> s[1]
5) 'u'
6) >>> s[-1]
7) 'a'
8) >>> s[40]
```

IndexError: string index out of range

```
1)  >>> s[1:40]
2)  'urga'
3)  >>> s[1:]
4)  'urga'
5)  >>> s[:4]
6)  'durg'
7)  >>> s[:]
8)  'durga'
9)  >>>
10)
11)
12) >>> s*3
13) 'durgadurgadurga'
14)
15) >>> len(s)
16) 5
```

Note:

1. In Python the following data types are considered as Fundamental Data types

- **int**
- **float**
- **complex**
- **bool**
- **str**

2. In Python, we can represent char values also by using str type and explicitly char type isnot available.

Eg:

```
1)  >>> c='a'
2)  >>> type(c)
3)  <class 'str'>
```

3. long Data Type is available in Python2 but not in Python3. In Python3 long values alsowe can represent by using int type only.

4. In Python we can present char Value also by using str Type and explicitly char Type isnot available.

Type Casting

We can convert one type value to another type. This conversion is called Typecasting or Type coercion.
The following are various inbuilt functions for type casting.

1. int()
2. float()
3. complex()
4. bool()
5. str()

1.int():

We can use this function to convert values from other types to

intEg:

```
1)  >>> int(123.987)
2)  123
3)  >>> int(10+5j)
4)  TypeError: can't convert complex to int
5)  >>> int(True)
6)  1
7)  >>> int(False)
8)  0
9)  >>> int("10")
10) 10
11) >>> int("10.5")
12) ValueError: invalid literal for int() with base 10: '10.5'
13) >>> int("ten")
14) ValueError: invalid literal for int() with base 10: 'ten'
15) >>> int("0B1111")
16) ValueError: invalid literal for int() with base 10: '0B1111'
```

Note:

1. We can convert from any type to int except complex type.

2. If we want to convert str type to int type, compulsary str should contain only integralvalue and should be specified in base-10

2. float():

We can use float() function to convert other type values to float type.

```
1)  >>> float(10)
2)  10.0
3)  >>> float(10+5j)
4)  TypeError: can't convert complex to float
5)  >>> float(True)
6)  1.0
7)  >>> float(False)
8)  0.0
9)  >>> float("10")
10) 10.0
11) >>> float("10.5")
12) 10.5
13) >>> float("ten")
14) ValueError: could not convert string to float: 'ten'
15) >>> float("0B1111")
16) ValueError: could not convert string to float: '0B1111'
```

Note:
1. We can convert any type value to float type except complex type.

2. Whenever we are trying to convert str type to float type compulsory str should beeither integral or floating point literal and should be specified only in base-10.

3.complex():

We can use complex() function to convert other types to complex type.

Form-1: complex(x)
We can use this function to convert x into complex number with real part x and imaginary part 0.

Eg:

```
1)  complex(10)==>10+0j
2)  complex(10.5)===>10.5+0j
3)  complex(True)==>1+0j
4)  complex(False)==>0j
5)  complex("10")==>10+0j
6)  complex("10.5")==>10.5+0j
7)  complex("ten")
8)     ValueError: complex() arg is a malformed string
```

Form-2: complex(x,y)

We can use this method to convert x and y into complex number such that x will be real part and y will be imaginary part.
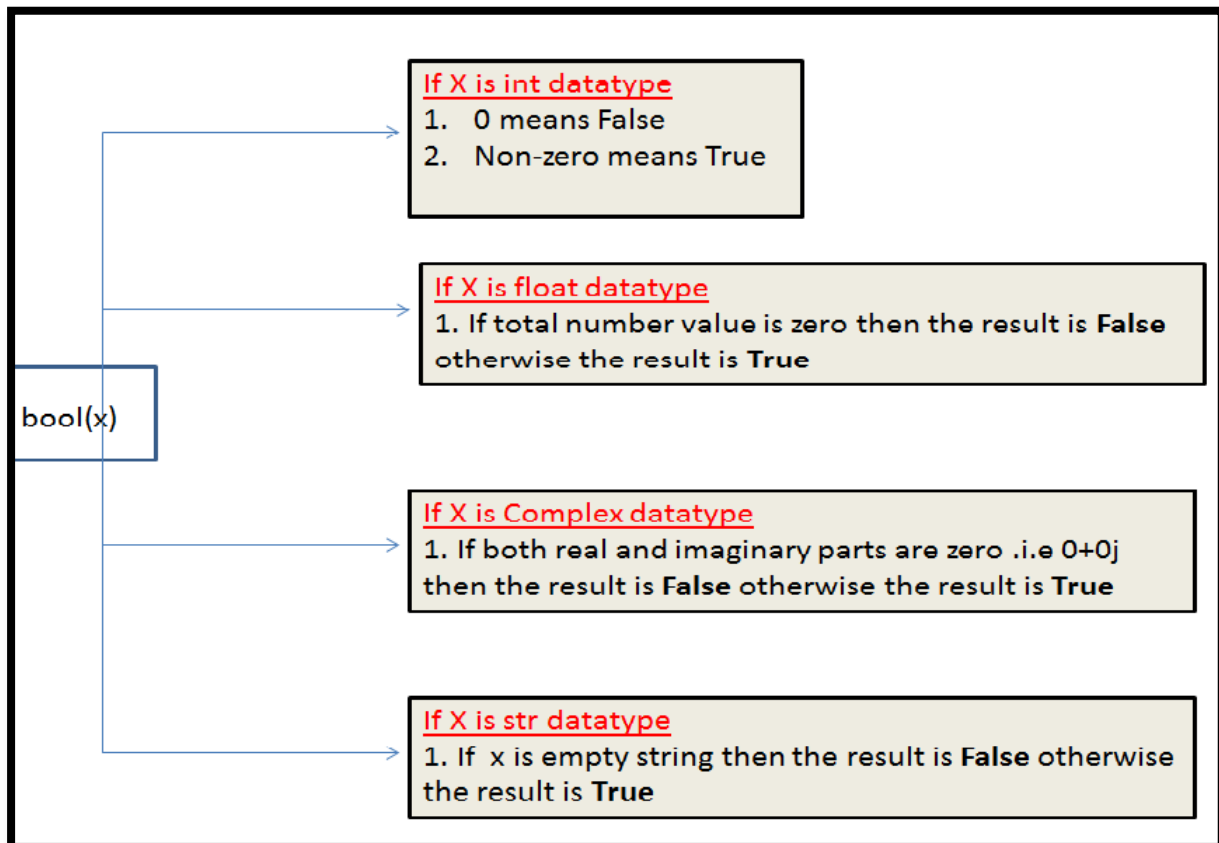

Eg: complex(10,-2)==>10-2j
complex(True,False)==>1+0j

4. bool():

We can use this function to convert other type values to bool type.

Eg:

1) bool(0)==>False
2) bool(1)==>True
3) bool(10)===>True
4) bool(10.5)===>True
5) bool(0.178)==>True
6) bool(0.0)==>False
7) bool(10-2j)==>True
8) bool(0+1.5j)==>True
9) bool(0+0j)==>False
10) bool("True")==>True
11) bool("False")==>True
12) bool("")==>False

If X is int datatype
1. 0 means False
2. Non-zero means True

If X is float datatype
1. If total number value is zero then the result is **False** otherwise the result is **True**

bool(x)

If X is Complex datatype
1. If both real and imaginary parts are zero .i.e 0+0j then the result is **False** otherwise the result is **True**

If X is str datatype
1. If x is empty string then the result is **False** otherwise the result is **True**

5. str():

We can use this method to convert other type values to str

typeEg:

```
1)  >>> str(10)
2)  '10'
3)  >>> str(10.5)
4)  '10.5'
5)  >>> str(10+5j)
6)  '(10+5j)'
7)  >>> str(True)
8)  'True'
```

Fundamental Data Types vs Immutability:

All Fundamental Data types are immutable. i.e once we creates an object,we cannot perform any changes in that object. If we are trying to change then with those changes anew object will be created. This non-chageable behaviour is called immutability.

In Python if a new object is required, then PVM won't create object immediately. First it will check is any object available with the required content or not. If available then existing object will be reused. If it is not available then only a new object will be created.The advantage of this approach is memory utilization and performance will be improved.

But the problem in this approach is, several references pointing to the same object, by using one reference if we are allowed to change the content in the existing object then theremaining references will be effected. To prevent this immutability concept is required.
According to this once creates an object we are not allowed to change content. If we aretrying to change with those changes a new object will be created.

Eg:

```
1)  >>> a=10
2) >>> b=10
3)  >>> a is b
4) True
5)  >>> id(a)
6) 1572353952
7)  >>> id(b)
8) 1572353952
9)  >>>
```

>>> a=10	>>> a=10+5j	>>> a=True	>>> a='durga'
>>> b=10	>>> b=10+5j	>>> b=True	>>> b='durga'
>>> id(a)	>>> a is b	>>> a is b	>>> a is b
1572353952	False	True	True
>>> id(b)	>>> id(a)	>>> id(a)	>>> id(a)
1572353952	15980256	1572172624	16378848
>>> a is b	>>> id(b)	>>> id(b)	>>> id(b)
True	15979944	1572172624	16378848

bytes Data Type:

bytes data type represents a group of byte numbers just like an

array.Eg:

```
1)  x = [10,20,30,40]
2)    b = bytes(x)
3)    type(b)==>bytes
4)    print(b[0])==> 10
5)    print(b[-1])==> 40
6)    >>> for i in b : print(i)
7)
8)      10
9)      20
10)     30
11)     40
```

Conclusion 1:

The only allowed values for byte data type are 0 to 256. By mistake if we are trying toprovide any other values then we will get value error.

Conclusion 2:

Once we creates bytes data type value, we cannot change its values, otherwise we will getTypeError.

Eg:

```
1)  >>> x=[10,20,30,40]
2)  >>> b=bytes(x)
3)  >>> b[0]=100
4)   TypeError: 'bytes' object does not support item assignment
```

bytearray Data type:

bytearray is exactly same as bytes data type except that its elements can be modified.

Eg 1:

```
1)  x=[10,20,30,40]
2)  b = bytearray(x)
3)  for i in b : print(i)
4)  10
```

```
5)  20
6) 30
7)  40
8)  b[0]=100
9)  for i in b: print(i)
10) 100
11) 20
12) 30
13) 40
```

Eg 2:

```
1)  >>> x =[10,256]
2) >>> b = bytearray(x)
3)  ValueError: byte must be in range(0, 256)
```

list data type:

If we want to represent a group of values as a single entity where insertion order requiredto preserve and duplicates are allowed then we should go for list data type.

1. insertion order is preserved
2. heterogeneous objects are allowed
3. duplicates are allowed
4. Growable in nature
5. values should be enclosed within square brackets.

Eg:

```
1)  list=[10,10.5,'durga',True,10]
2)     print(list) # [10,10.5,'durga',True,10]
```

Eg:

```
1)  list=[10,20,30,40]
2) >>> list[0]
3)  10
4) >>> list[-1]
5)  40
6) >>> list[1:3]
7)  [20, 30]
8) >>> list[0]=100
9)  >>> for i in list:print(i)
10) ...
11) 100
12) 20
13) 30
```

14) 40

list is growable in nature. i.e based on our requirement we can increase or decrease the size.

1) >>> list=[10,20,30]
2) >>> list.append("durga")
3) >>> list
4) [10, 20, 30, 'durga']
5) >>> list.remove(20)
6) >>> list
7) [10, 30, 'durga']
8) >>> list2=list*2
9) >>> list2
10) [10, 30, 'durga', 10, 30, 'durga']

Note: **An ordered, mutable, heterogenous collection of eleemnts is nothing but list, whereduplicates also allowed.**

tuple data type:

tuple data type is exactly same as list data type except that it is immutable.i.e we cannotchage values.

Tuple elements can be represented within parenthesis.

Eg:

1)   t=(10,20,30,40)
2)   type(t)
3) <class 'tuple'>
4)   t[0]=100
5) TypeError: 'tuple' object does not support item assignment
6) >>> t.append("durga")
7)   AttributeError: 'tuple' object has no attribute 'append'
8) >>> t.remove(10)
9)   AttributeError: 'tuple' object has no attribute 'remove'

Note: **tuple is the read only version of list**

range Data Type:

range Data Type represents a sequence of numbers.
The elements present in range Data type are not modifiable. i.e range Data type isimmutable.

Form-1: range(10)
generate numbers from 0 to 9

Eg:
r=range(10)
for i in r : print(i) 0 to 9

Form-2: range(10,20)

generate numbers from 10 to

19r = range(10,20)
for i in r : print(i) 10 to 19

Form-3: range(10,20,2)

2 means increment

valuer = range(10,20,2)
for i in r : print(i) 10,12,14,16,18

We can access elements present in the range Data Type by using index.
r=range(10,20)
r[0]==>10
r[15]==>IndexError: range object index out of

rangeWe cannot modify the values of range data

type

Eg:
r[0]=100
TypeError: 'range' object does not support item

assignmentWe can create a list of values with range data

type

Eg:

```
1)  >>> l = list(range(10))
2) >>> l
3)  [0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

set Data Type:

If we want to represent a group of values without duplicates where order is not important then we should go for set Data Type.

1. insertion order is not preserved
2. duplicates are not allowed
3. heterogeneous objects are allowed
4. index concept is not applicable
5. It is mutable collection
6. Growable in

nature**Eg:**

```
1)   s={100,0,10,200,10,'durga'}
2)   s # {0, 100, 'durga', 200, 10}
3)  s[0] ==>TypeError: 'set' object does not support indexing
4)
5)  set is growable in nature, based on our requirement we can increase or decrease the size.
6)
7)  >>> s.add(60)
8)  >>> s
9)  {0, 100, 'durga', 200, 10, 60}
10) >>> s.remove(100)
11) >>> s
12) {0, 'durga', 200, 10, 60}
```

frozenset Data Type:

It is exactly same as set except that it is
immutable.Hence, we cannot use add or remove
functions.

```
1)  >>> s={10,20,30,40}
2)  >>> fs=frozenset(s)
3)  >>> type(fs)
4)  <class 'frozenset'>
5)  >>> fs
6)  frozenset({40, 10, 20, 30})
7)  >>> for i in fs:print(i)
8)  ...
9)   40
10) 10
11) 20
12) 30
13)
14) >>> fs.add(70)
15) AttributeError: 'frozenset' object has no attribute 'add'
16) >>> fs.remove(10)
17) AttributeError: 'frozenset' object has no attribute 'remove'
```

dict Data Type:

If we want to represent a group of values as key-value pairs then we should go for dictdata type.

Eg:
d={101:'durga',102:'ravi',103:'shiva'}

Duplicate keys are not allowed but values can be duplicated. If we are trying to insert an entry with duplicate key then old value will be replaced with new value.

Eg:

```
1.  >>> d={101:'durga',102:'ravi',103:'shiva'}
2.  >>> d[101]='sunny'
3.  >>> d
4.  {101: 'sunny', 102: 'ravi', 103: 'shiva'}
5.
6.  We can create empty dictionary as follows
7.  d={ }
8.  We can add key-value pairs as follows
9.  d['a']='apple'
10. d['b']='banana'
11. print(d)
```

Note: dict is mutable and the order won't be preserved.

Note:

1. In general we can use bytes and bytearray data types to represent binary informationlike images,video files etc
2. In Python2 long data type is available. But in Python3 it is not available and we canrepresent long values also by using int type only.
3. In Python there is no char data type. Hence, we can represent char values also by usingstr type.

Summary of Datatypes in Python3

Datatype	Description	Is Immutable	Example

Int	We can use to represent the whole/integral numbers	Immutable	>>> a=10
			>>> type(a)
			<class 'int'>

Float	We can use to represent thedecimal/floating point numbers	Immutable	>>> b=10.5
			>>> type(b)
			<class 'float'>

Complex	We can use to represent the complex numbers	Immutable	>>> c=10+5j
			>>> type(c)
			<class 'complex'>
			>>>
			c.real
			10.0
			>>>
			c.imag5.0

Bool	We can use to represent the logical values(Only allowed values are True and False)	Immutable	>>> flag=True
			>>> flag=False
			>>> type(flag)
			<class 'bool'>

Str	To represent sequence of Characters	Immutable	>>> s='durga'
			>>> type(s)
			<class 'str'>
			>>> s="durga"
			>>> s="'Durga Software Solutions
			... Ameerpet"'
			>>> type(s)
			<class 'str'>

bytes	To represent a sequence ofbyte values from 0-255	Immutable	>>> list=[1,2,3,4]
			>>> b=bytes(list)
			>>> type(b)
			<class 'bytes'>

bytearray	To represent a sequence ofbyte values from 0-255	Mutable	>>> list=[10,20,30]
			>>> ba=bytearray(list)
			>>> type(ba)
			<class 'bytearray'>

range	To represent a range of values	Immutable	>>> r=range(10)
			>>> r1=range(0,10)
			>>> r2=range(0,10,2)

list	To represent an ordered collection of objects	Mutable	>>> l=[10,11,12,13,14,15]
			>>> type(l)
			<class 'list'>

tuple	To represent an ordered collections of objects	Immutable	>>> t=(1,2,3,4,5)
			>>> type(t)
			<class 'tuple'>

set	To represent an unordered collection of unique objects	Mutable	>>> s={1,2,3,4,5,6} >>> type(s)

			<class 'set'>

frozenset	To represent an unordered collection of unique objects	Immutable	>>> s={11,2,3,'Durga',100,'Ramu'}
			 >>> fs=frozenset(s)
			 >>> type(fs)
			 <class 'frozenset'>

dict	To represent a group of keyvalue pairs	Mutable	>>> d={101:'durga',102:'ramu',103:'hari'} >>> type(d) <class 'dict'>

None Data Type:

None means Nothing or No value associated.
If the value is not available, then to handle such type of cases None
introduced.It is something like null value in Java.
Eg:
def m1():
  a=10

print(m1()
)None

Escape Characters:

In String literals we can use escape characters to associate a special meaning.

```
1)  >>> s="durga\nsoftware"
2)  >>> print(s)
3)  durga
4)  software
5)  >>> s="durga\tsoftware"
6)  >>> print(s)
7)  durga   software
8)  >>> s="This is " symbol"
9)     File "<stdin>", line 1
10)     s="This is " symbol"
11)                 ^
12)  SyntaxError: invalid syntax
13)  >>> s="This is \" symbol"
14)  >>> print(s)
15)  This is " symbol
```

The following are various important escape characters in Python

1) \n==>New Line
2) \t===>Horizontal tab
3) \r ==>Carriage Return
4) \b===>Back space
5) \f===>Form Feed
6) \v==>Vertical tab
7) \'===>Single quote
8) \"===>Double quote
9) \\===>back slash symbol
....

Constants:

Constants concept is not applicable in Python.
But it is convention to use only uppercase characters if we don't want to change

value.MAX_VALUE=10

It is just convention but we can change the value.

python™

Operators

Operator is a symbol that performs certain operations. Python provides the following set of operators

1. **Arithmetic Operators**
2. **Relational Operators or Comparison Operators**
3. **Logical operators**
4. **Bitwise operators**
5. **Assignment operators**
6. **Special operators**

1. Arithmetic Operators:

+ ==>Addition
- ==>Subtraction
* ==>Multiplication
/ ==>Division operator
% ===>Modulo operator

// ==>Floor Division operator

** ==>Exponent operator or power

operatorEg: test.py:

```
1)   a=10
2) b=2
3)   print('a+b=',a+b)
4) print('a-b=',a-b)
5)   print('a*b=',a*b)
6) print('a/b=',a/b)
7)   print('a//b=',a//b)
8) print('a%b=',a%b)
9)   print('a**b=',a**b)
```

Output:

1) **Python test.py   or py test.py**
2) **a+b= 12**
3) **a-b= 8**
4) **a*b= 20**
5) **a/b= 5.0**
6) **a//b= 5**
7) **a%b= 0**
8) **a**b= 100**

Eg:

1) **a = 10.5**
2) **b=2**
3)
4) **a+b= 12.5**
5) **a-b= 8.5**
6) **a*b= 21.0**
7) **a/b= 5.25**
8) **a//b= 5.0**
9) **a%b= 0.5**
10) **a**b= 110.25**

Eg:
10/2==>5.0
10//2==>5
10.0/2===>5.0
10.0//2===>5.0

Note: **/ operator always performs floating point arithmetic. Hence it will always returnfloat value.**

But Floor division (//) can perform both floating point and integral arithmetic. If arguments are int type then result is int type. If at least one argument is float type, thenresult is float type.

Note:

We can use +,* operators for str type also.
If we want to use + operator for str type then compulsory both arguments should be str type only otherwise we will get error.

1) **>>> "durga"+10**
2) **TypeError: must be str, not int**
3) **>>> "durga"+"10"**
4) **'durga10'**

If we use * operator for str type then compulsory one argument should be int and other argument should be str type.

**2*"durga
"
"durga"*
2
2.5*"durga" ==>TypeError: can't multiply sequence by non-int of type 'float'
"durga"*"durga"==>TypeError: can't multiply sequence by non-int of type 'str'**

**+====>String concatenation operator
* ===>String multiplication operator**

Note: For any number x,

x/0 and x%0 always raises

**"ZeroDivisionError"10/0
10.0/0
.....**

Relational Operators:

>,>=,<,<

=Eg 1:

```
1)  a=10
2) b=20
3)   print("a > b is ",a>b)
4) print("a >= b is ",a>=b)
5)   print("a < b is ",a<b)
6) print("a <= b is ",a<=b)
7)
8) a > b is  False
9)  a >= b is  False
10) a < b is  True
11)  a <= b is  True
```

We can apply relational operators for str types

also**Eg 2:**

```
1)  a="durga"
2) b="durga"
3)   print("a > b is ",a>b)
4) print("a >= b is ",a>=b)
5)   print("a < b is ",a<b)
```

```
6)  print("a <= b is ",a<=b)
7)
8)  a > b is  False
9)  a >= b is  True
10) a < b is False
11) a <= b is  True
```

Eg:

```
1)  print(True>True)   False
2)  print(True>=True)   True
3)  print(10 >True) True
4)  print(False > True) False
5)
6)  print(10>'durga')
7)      TypeError: '>' not supported between instances of 'int' and 'str'
```

Eg:

```
1)  a=10
2)  b=20
3)  if(a>b):
4)      print("a is greater than b")
5)  else:
6)      print("a is not greater than b")
```

Output: a is not greater than b

Note: Chaining of relational operators is possible. In the chaining, if all comparisons return True then only result is True. If at least one comparison returns False then theresult is False

Eg:

```
1)  10<20 ==>True
2)  10<20<30  ==>True
3)  10<20<30<40  ==>True
4)  10<20<30<40>50 ==>False
```

equality operators:
== , !=

We can apply these operators for any type even for incompatible types also

```
1)  >>> 10==20
2)  False
3)  >>> 10!= 20
```

4) **True**
5) **>>> 10==True**
6) **False**
7) **>>> False==False**
8) **True**
9) **>>> "durga"=="durga"**
10) **True**
11) **>>> 10=="durga"**
12) **False**

Note: **Chaining concept is applicable for equality operators. If at least one comparison returns False then the result is False. otherwise, the result is True.**

Eg:

1) **>>> 10==20==30==40**
2) **False**
3) **>>> 10==10==10==10**
4) **True**

Logical Operators:

and, or ,not

We can apply for all types.

For boolean types behaviour:

and ==>If both arguments are True then only result is True or ====>If atleast one arugemnt is True then result is Truenot ==>complement

True and False
==>FalseTrue or False
===>True not False
==>True

For non-boolean types behaviour:

0 means False
non-zero means True
empty string is always treated as False

x and y:

==>if x is evaluating to false return x otherwise returns y

Eg:
10 and 20
0 and 20

If first argument is zero then result is zero otherwise result is y

x or y:

If x evaluates to True then result is x otherwise result is y

10 or 20 ==> 10
0 or 20 ==> 20

not x:

If x is evalutates to False then result is True otherwise False

not 10 ==>False

not 0

==>TrueEg:

1) **"durga" and "durgasoft" ==>durgasoft**
2) **"" and "durga" ==>""**
3) **"durga" and "" ==>""**
4) **"" or "durga" ==>"durga"**
5) **"durga" or ""==>"durga"**
6) **not ""==>True**
7) **not "durga" ==>False**

Bitwise Operators:

We can apply these operators bitwise.
These operators are applicable only for int and Boolean types.
By mistake if we are trying to apply for any other type then we will get Error.

&,|,^,~,<<,>>

print(4&5)
==>valid print(10.5
& 5.6) ==>
        TypeError: unsupported operand type(s) for &: 'float' and 'float'

print(True & True) ==>valid

& ==> If both bits are 1 then only result is 1 otherwise result is 0
| ==> If atleast one bit is 1 then result is 1 otherwise result is 0
^ ==>If bits are different then only result is 1 otherwise result is 0
~ ==>bitwise complement
operator1==>0 & 0==>1
<< ==>Bitwise Left shift
>> ==>Bitwise Right Shift

print(4&5) ==>4
print(4|5) ==>5
print(4^5) ==>1

Operator	Description
&	If both bits are 1 then only result is 1 otherwise result is 0
|	If atleast one bit is 1 then result is 1 otherwise result is 0
^	If bits are different then only result is 1 otherwise result is 0
~	bitwise complement operator i.e 1 means 0 and 0 means 1
>>	Bitwise Left shift Operator
<<	Bitwise Right shift Operator

bitwise complement operator(~):

We have to apply complement for total

bits.Eg: print(~5) ==>-6

Note:
The most significant bit acts as sign bit. 0 value represents +ve number where as 1represents -ve value.
**positive numbers will be represented directly in the memory whereas -ve numbers will berepresented indirectly in 2's complement form.**

Shift Operators:

<< Left shift operator
After shifting the empty cells we have to fill with zero

print(10<<2)==>40

0	0	0	0	1	0	1	0

0	0	1	0	1	0	0	0

## >> Right Shift operator

After shifting the empty cells we have to fill with sign bit.(0 for +ve and 1 for -

ve)print(10>>2) ==>2

0	0	0	0	1	0	1̶	0̶

0	0	0	0	0	0	1	0

We can apply bitwise operators for boolean types

alsoprint(True & False) ==>False
print(True | False)
===>Trueprint(True ^
False) ==>True
print(~True)   ==>-2
print(True<<2)   ==>4
print(True>>2)   ==>0

Assignment Operators:

We can use assignment operator to assign value to the variable.

Eg:
x=10

 We can combine assignment operator with some other operator to form compoundassignment operator.

Eg: x+=10 ====> x = x+10

 The following is the list of all possible compound assignment operators in Python

+=
-=
*=
/=
%=
//=
**=
&=
|=
^=

```
>>=
<<=
```

Eg:

```
1) x=10
2) x+=20
3) print(x) ==>30
```

Eg:

```
1) x=10
2) x&=5
3) print(x) ==>0
```

Ternary Operator:

Syntax:
x = firstValue if condition else secondValue

If condition is True then firstValue will be considered else secondValue will be considered.

Eg 1:

```
1) a,b=10,20
2) x=30 if a<b else 40
3) print(x)   #30
```

Eg 2: Read two numbers from the keyboard and print minimum value

```
1) a=int(input("Enter First Number:"))
2) b=int(input("Enter Second Number:"))
3) min=a if a<b else b
4) print("Minimum Value:",min)
```

Output:
Enter First Number:10
Enter Second
Number:30Minimum
Value: 10

Note: Nesting of ternary operator is possible.

Q. Program for minimum of 3 numbers

```python
1)  a=int(input("Enter First Number:"))
2)  b=int(input("Enter Second Number:"))
3)  c=int(input("Enter Third Number:"))
4)  min=a if a<b and a<c else b if b<c else c
5)  print("Minimum Value:",min)
```

Q. Program for maximum of 3 numbers

```python
1)  a=int(input("Enter First Number:"))
2)  b=int(input("Enter Second Number:"))
3)  c=int(input("Enter Third Number:"))
4)  max=a if a>b and a>c else b if b>c else c
5)  print("Maximum Value:",max)
```

Eg:

```python
1)  a=int(input("Enter First Number:"))
2)  b=int(input("Enter Second Number:"))
3)  print("Both numbers are equal" if a==b else "First Number is Less than Second Number" if
    a<b else "First Number Greater than Second Number")
```

Output:
D:\python_classes>py test.py
Enter First Number:10
Enter Second
Number:10Both
numbers are equal

D:\python_classes>py test.py
Enter First Number:10
Enter Second Number:20
First Number is Less than Second Number

D:\python_classes>py test.py
Enter First Number:20
Enter Second Number:10
First Number Greater than Second Number

Special operators:

Python defines the following 2 special operators

1. Identity Operators
2. Membership operators

1. Identity Operators

We can use identity operators for address
comparison.2 identity operators are available
1. is
2. is not

r1 is r2 returns True if both r1 and r2 are pointing to the same object
r1 is not r2 returns True if both r1 and r2 are not pointing to the same

object**Eg:**

```
1)   a=10
2)  b=10
3)   print(a is b)     True
4)  x=True
5)  y=True
6)   print( x is y)    True
```

Eg
:

```
1)   a="durga"
2)  b="durga"
3)  print(id(a))
4)  print(id(b))
5)  print(a is b)
```

Eg
:

```
1)  list1=["one","two","three"]
2)  list2=["one","two","three"]
3)  print(id(list1))
4)  print(id(list2))
5)  print(list1 is list2)  False
6)  print(list1 is not list2)  True
7)  print(list1 == list2)   True
```

Note:
We can use is operator for address comparison whereas == operator for content comparison.

2. Membership operators:

We can use Membership operators to check whether the given object present in thegiven collection.(It may be String,List,Set,Tuple or Dict)

in ☐ Returns True if the given object presents in the specified Collection
not in ☐ Retruns True if the given object not present in the specified Collection

Eg:

1) x="hello learning Python is very easy!!!"
2) print('h' in x) True
3) print('d' in x) False
4) print('d' not in x)   True
5) print('Python' in x)   True

Eg:

1) list1=["sunny","bunny","chinny","pinny"]
2) print("sunny" in list1) True
3) print("tunny" in list1) False
4) print("tunny" not in list1) True

Operator Precedence:

If multiple operators present then which operator will be evaluated first is decided by operator precedence.

Eg:
print(3+10*2) ☐ 23
print((3+10)*2) ☐ 26

The following list describes operator precedence in

Python() ☐ Parenthesis
** ☐ exponential operator
~,- ☐ Bitwise complement operator,unary minus operator
*,/,%,// ☐ multiplication,division,modulo,floor division
+,- ☐ addition,subtraction
<<,>> ☐ Left and Right
Shift& ☐ bitwise And

^ → Bitwise X-OR
| → Bitwise OR
>,>=,<,<=, ==, != ==>Relational or Comparison operators
=,+=,-=,*=... ==>Assignment
operatorsis , is not → Identity
Operators
in , not in → Membership operators
not → Logical not
and → Logical and
or → Logical or

Eg:

```
1)  a=30
2)  b=20
3)  c=10
4)  d=5
5)  print((a+b)*c/d)      100.0
6)  print((a+b)*(c/d))    100.0
7)  print(a+(b*c)/d)       70.0
8)
9)
10) 3/2*4+3+(10/5)**3-2
11) 3/2*4+3+2.0**3-2
12) 3/2*4+3+8.0-2
13) 1.5*4+3+8.0-2
14) 6.0+3+8.0-2
15) 15.0
```

Mathematical Functions (math Module)

A Module is collection of functions, variables and classes etc.

math is a module that contains several functions to perform mathematical

operationsIf we want to use any module in Python, first we have to import that

module.

import math

Once we import a module then we can call any function of that module.

```
import math
print(math.sqrt(16))
print(math.pi)
```

```
4.0
3.141592653589793
```

We can create alias name by using as

keyword.import math as m

Once we create alias name, by using that we can access functions and variables of thatmodule

```
import math as m
print(m.sqrt(16))
print(m.pi)
```

We can import a particular member of a module explicitly as follows

```
from math import sqrt
from math import sqrt,pi
```

If we import a member explicitly then it is not required to use module name whileaccessing.

```
from math import
sqrt,piprint(sqrt(16))
print(pi)
print(math.pi) 
```
NameError: name 'math' is not defined

important functions of math module:

ceil(x)
floor(x)
pow(x,y)
factorial(x
)trunc(x)
gcd(x,y)
sin(x)
cos(x)
tan(x)
....

important variables of math module:

pi3.14
e===>2.7
1
inf ==>infinity
nan ==>not a number

Q. Write a Python program to find area of circle

pi*r2**

from math import
pir=16
print("Area of Circle is :",pi*r2)**

OutputArea of Circle is :

804.247719318987

Input And Output Statements

Reading dynamic input from the keyboard:

In Python 2 the following 2 functions are available to read dynamic input from thekeyboard.

  1. raw_input()
  2. input()

1. raw_input():

  This function always reads the data from the keyboard in the form of String Format. Wehave to convert that string type to our required type by using the corresponding type casting methods.

Eg:
  x=raw_input("Enter First Number:")
  print(type(x))   It will always print str type only for any input type

2. input():

  input() function can be used to read data directly in our required format. We are not required to perform type casting.

  x=input("Enter
  Value)type(x)

  10 ===> int
  "durga"===>s
  tr
  10.5===>float
  True==>bool

  ***Note: But in Python 3 we have only input() method and raw_input() method is not available.
  Python3 input() function behaviour exactly same as raw_input() method of Python2. i.eevery input value is treated as str type only.

  raw_input() function of Python 2 is renamed as input() function in Python3

Eg:

```
1)    >>> type(input("Enter value:"))
2)  Enter value:10
3)  <class 'str'>
4)
5)  Enter value:10.5
6)  <class 'str'>
7)
8)  Enter value:True
9)  <class 'str'>
```

Q. Write a program to read 2 numbers from the keyboard and print sum.

```
1)  x=input("Enter First Number:")
2)  y=input("Enter Second Number:")
3)  i = int(x)
4)  j = int(y)
5)  print("The Sum:",i+j)
6)
7)  Enter First Number:100
8)  Enter Second Number:200
9)  The Sum: 300
```

```
1)  x=int(input("Enter First Number:"))
2)  y=int(input("Enter Second Number:"))
3)  print("The Sum:",x+y)
```

```
1)  print("The Sum:",int(input("Enter First Number:"))+int(input("Enter Second
    Number:")))
```

Q. Write a program to read Employee data from the keyboard and print that data.

```
1)   eno=int(input("Enter Employee No:"))
2)   ename=input("Enter Employee Name:")
3)   esal=float(input("Enter Employee Salary:"))
4)   eaddr=input("Enter Employee Address:")
5)   married=bool(input("Employee Married ?[True|False]:"))
6)   print("Please Confirm Information")
7)   print("Employee No :",eno)
8)   print("Employee Name :",ename)
9)   print("Employee Salary :",esal)
10)  print("Employee Address :",eaddr)
11)  print("Employee Married ? :",married)
12)
```

13) D:\Python_classes>py test.py
14) Enter Employee No:100
15) Enter Employee Name:Sunny
16) Enter Employee Salary:1000
17) Enter Employee Address:Mumbai
18) Employee Married ?[True|False]:True
19) Please Confirm Information
20) Employee No : 100
21) Employee Name : Sunny
22) Employee Salary : 1000.0
23) Employee Address : Mumbai
24) Employee Married ? : True

How to read multiple values from the keyboard in a single line:

1) a,b= [int(x) for x in input("Enter 2 numbers :").split()]
2) print("Product is :", a*b)
3)
4) D:\Python_classes>py test.py
5) Enter 2 numbers :10 20
6) Product is : 200

Note: split() function can take space as separator by default   .But we can passanything as separator.

Q. Write a program to read 3 float numbers from the keyboard with , seperator and printtheir sum.

1) a,b,c= [float(x) for x in input("Enter 3 float numbers :").split(',')]
2) print("The Sum is :", a+b+c)
3)
4) D:\Python_classes>py test.py
5) Enter 3 float numbers :10.5,20.6,20.1
6) The Sum is : 51.2

eval():

eval Function take a String and evaluate the Result.

Eg: x = eval("10+20+30")
   print(x)

   Output: 60

Eg: x = eval(input("Enter
   Expression"))Enter Expression:
   10+2*3/4 Output11.5

eval() can evaluate the Input to list, tuple, set, etc based the provided

Input.Eg: Write a Program to accept list from the keyboard on the display

```
1)  l = eval(input("Enter List"))
2)  print (type(l))
3)  print(l)
```

Command Line Arguments

- **argv is not Array it is a List. It is available sys Module.**
- **The Argument which are passing at the time of execution are called Command LineArguments.**

Eg: D:\Python_classes py test.py 10 20 30

Command Line Arguments

Within the Python Program this Command Line Arguments are available in argv. Which ispresent in SYS Module.

test.py	10	20	30

Note: argv[0] represents Name of Program. But not first Command Line Argument.argv[1] represent First Command Line Argument.

Program: To check type of argv from

sysimport argv
print(type(argv))

D:\Python_classes\py test.py

Write a Program to display Command Line Arguments

```
1)  from sys import argv
2)  print("The Number of Command Line Arguments:", len(argv))
3)  print("The List of Command Line Arguments:", argv)
4)  print("Command Line Arguments one by one:")
5)  for x in argv:
6)      print(x)
7)
8)  D:\Python_classes>py test.py 10 20 30
9)  The Number of Command Line Arguments: 4
```

```
10) The List of Command Line Arguments: ['test.py', '10','20','30']
11) Command Line Arguments one by one:
12) test.py
13) 10
14) 20
15) 30
```

```python
1)  from sys import argv
2)  sum=0
3)  args=argv[1:]
4)  for x in args  :
5)     n=int(x)
6)     sum=sum+n
7)  print("The Sum:",sum)
8)
9)  D:\Python_classes>py test.py 10 20 30 40
10) The Sum: 100
```

Note1: usually space is seperator between command line arguments. If our command lineargument itself contains space then we should enclose within double quotes(but not single quotes)

Eg:

```python
1)  from sys import argv
2)  print(argv[1])
3)
4)  D:\Python_classes>py test.py Sunny Leone
5)  Sunny
6)
7)  D:\Python_classes>py test.py 'Sunny Leone'
8)  'Sunny
9)
10) D:\Python_classes>py test.py "Sunny Leone"
11) Sunny Leone
```

Note2: Within the Python program command line arguments are available in the Stringform. Based on our requirement,we can convert into corresponding type by using type casting methods.

Eg:

```python
1)  from sys import argv
2) print(argv[1]+argv[2])
3)  print(int(argv[1])+int(argv[2]))
```

```
4)
5) D:\Python_classes>py test.py 10 20
6) 1020
7) 30
```

Note3: If we are trying to access command line arguments with out of range index thenwe will get Error.

Eg:

```
1)  from sys import argv
2) print(argv[100])
3)
4) D:\Python_classes>py test.py 10 20
5)   IndexError: list index out of range
```

Note:

In Python there is argparse module to parse command line arguments and display some help messages whenever end user enters wrong input.

input()
raw_input(
)

command line arguments

output statements:

We can use print() function to display output.

Form-1: print() without any argumentJust it prints new line character

Form-2:

```
1)  print(String):
2) print("Hello World")
3)  We can use escape characters also
4) print("Hello \n World")
5) print("Hello\tWorld")
6)  We can use repetetion operator (*) in the string
7) print(10*"Hello")
8) print("Hello"*10)
9)  We can use + operator also
10) print("Hello"+"World")
```

Note:
If both arguments are String type then + operator acts as concatenation operator.

If one argument is string type and second is any other type like int then we will get

Error If both arguments are number type then + operator acts as arithmetic addition

operator. **Note:**

```
1)  print("Hello"+"World")
2) print("Hello","World")
3)
4) HelloWorld
5)    Hello World
```

Form-3: print() with variable number of arguments:

```
1.  a,b,c=10,20,30
2.  print("The Values are :",a,b,c)
3.
4.  OutputThe Values are : 10 20 30
```

By default output values are seperated by space.If we want we can specify seperator byusing "sep" attribute

```
1.  a,b,c=10,20,30
2.  print(a,b,c,sep=',')
3.  print(a,b,c,sep=':')
4.
5. D:\Python_classes>py test.py
6.  10,20,30
7. 10:20:30
```

Form-4: print() with end attribute:

```
1.  print("Hello")
2. print("Durga")
3.  print("Soft")
```

Output:

```
1.  Hello
2. Durga
3.  Soft
```

If we want output in the same line with space

```
1.  print("Hello",end=' ')
2.  print("Durga",end=' ')
3.  print("Soft")
```

Output: Hello Durga Soft

Note: The default value for end attribute is \n,which is nothing but new line character.

Form-5: print(object) statement:

We can pass any object (like list,tuple,set etc)as argument to the print()

statement.**Eg:**

```
1.  l=[10,20,30,40]
2.  t=(10,20,30,40)
3.  print(l)
4.  print(t)
```

Form-6: print(String,variable list):

We can use print() statement with String and any number of

arguments.**Eg:**

```
1.  s="Durga"
2.  a=48
3.  s1="java"
4.  s2="Python"
5.  print("Hello",s,"Your Age is",a)
6.  print("You are teaching",s1,"and",s2)
```

Output:

```
1)  Hello Durga Your Age is 48
2)  You are teaching java and Python
```

Form-7: print(formatted string):

%i====>int
%d====>int
%f=====>float
%s======>String type

Syntax:

print("formatted string" %(variable list))Eg 1:

```
1)  a=10
2)  b=20
3)  c=30
4)  print("a value is %i" %a)
5)  print("b  value is %d and c value is %d" %(b,c))
6)
7)  Output
8)  a value is 10
9)  b  value is 20 and c value is 30
```

Eg 2:

```
1)  s="Durga"
2)  list=[10,20,30,40]
3)  print("Hello %s ...The List of Items are %s"  %(s,list))
4)
5)  Output Hello Durga ...The List of Items are [10, 20, 30, 40]
```
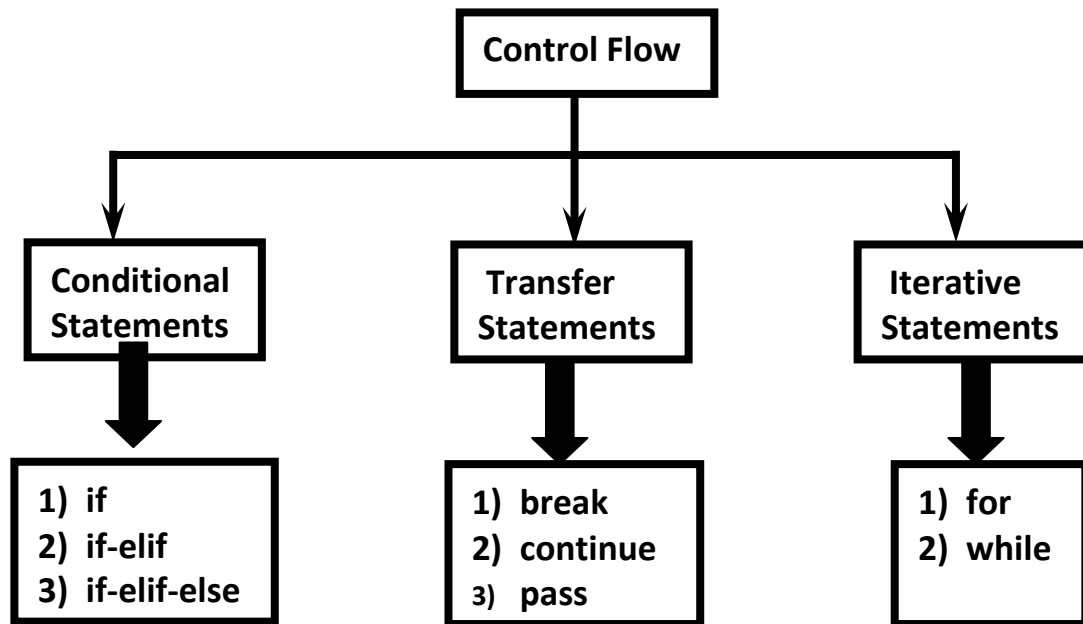

Form-8: print() with replacement operator {}

Eg:

```
1)  name="Durga"
2)  salary=10000
3)  gf="Sunny"
4)  print("Hello {0} your salary is {1} and Your Friend {2} is waiting".format(name,salary,gf))
5)  print("Hello {x} your salary is {y} and Your Friend {z} is waiting".format(x=name,y=salary,z=
      gf))
6)
7)  Output
8)  Hello Durga your salary is 10000 and Your Friend Sunny is waiting
9)  Hello Durga your salary is 10000 and Your Friend Sunny is waiting
```

Flow Control

Flow control describes the order in which statements will be executed at runtime.

```
                    ┌──────────────────┐
                    │   Control Flow   │
                    └──────────────────┘
          ┌──────────────────┼──────────────────┐
          ▼                  ▼                  ▼
┌──────────────┐   ┌──────────────┐   ┌──────────────┐
│ Conditional  │   │  Transfer    │   │  Iterative   │
│ Statements   │   │  Statements  │   │  Statements  │
└──────────────┘   └──────────────┘   └──────────────┘
       │                  │                  │
       ▼                  ▼                  ▼
┌──────────────┐   ┌──────────────┐   ┌──────────────┐
│ 1) if        │   │ 1) break     │   │ 1) for       │
│ 2) if-elif   │   │ 2) continue  │   │ 2) while     │
│ 3) if-elif-  │   │ 3) pass      │   │              │
│    else      │   │              │   │              │
└──────────────┘   └──────────────┘   └──────────────┘
```

I. Conditional Statements

1) if

if condition :

  statementor

if condition :
   statement-1
   statement-2
   statement-3
If condition is true then statements will be executed.

Eg:

```
1)   name=input("Enter Name:")
2) if name=="durga" :
3)       print("Hello Durga Good Morning")
4) print("How are you!!!")
5)
6) D:\Python_classes>py test.py
7)   Enter Name:durga
8) Hello Durga Good Morning
9)   How are you!!!
10)
11) D:\Python_classes>py test.py
12) Enter Name:Ravi
13)  How are you!!!
```

2) if-else:

if condition :
    Action-
1else :
    Action-2

if condition is true then Action-1 will be executed otherwise Action-2 will be

executed.Eg:

```
1)   name=input("Enter Name:")
2)   if name=="durga" :
3)       print("Hello Durga Good Morning")
4)   else:
5)       print("Hello Guest Good Moring")
6)   print("How are you!!!")
7)
8)   D:\Python_classes>py test.py
9)   Enter Name:durga
10)  Hello Durga Good Morning
11)  How are you!!!
12)
13)  D:\Python_classes>py test.py
14)  Enter Name:Ravi
15)  Hello Guest Good Moring
16)  How are you!!!
```

3) if-elif-else:

Syntax:

if condition1:
   Action-1
elif condition2:
   Action-2
elif condition3:
   Action-3
 elif condition4:
   Action-4

   ...
else:
   Default Action

Based condition the corresponding action will be

executed.Eg:

```
1)  brand=input("Enter Your Favourite Brand:")
2)  if brand=="RC" :
3)      print("It is childrens brand")
4)  elif brand=="KF":
5)      print("It is not that much kick")
6)  elif brand=="FO":
7)      print("Buy one get Free One")
8)  else :
9)      print("Other Brands are not recommended")
10)
11)
12) D:\Python_classes>py test.py
13) Enter Your Favourite Brand:RC
14) It is childrens brand
15)
16) D:\Python_classes>py test.py
17) Enter Your Favourite Brand:KF
18) It is not that much kick
19)
20) D:\Python_classes>py test.py
21) Enter Your Favourite Brand:KALYANI
22) Other Brands are not recommended
```

Note:

1. **else part is always optional**
   Hence the following are various possible syntaxes.
   1. if
   2. if - else
   3. if-elif-else
   4. if-elif

2. **There is no switch statement in Python**

Q. Write a program to find biggest of given 2 numbers from the commad prompt?

```
1) n1=int(input("Enter First Number:"))
2) n2=int(input("Enter Second Number:"))
3) if n1>n2:
4)     print("Biggest Number is:",n1)
5) else :
6)     print("Biggest Number is:",n2)
7)
8)   D:\Python_classes>py test.py
9)   Enter First Number:10
10) Enter Second Number:20
11) Biggest Number is: 20
```

Q. Write a program to find biggest of given 3 numbers from the commad prompt?

```
1) n1=int(input("Enter First Number:"))
2) n2=int(input("Enter Second Number:"))
3) n3=int(input("Enter Third Number:"))
4) if n1>n2 and n1>n3:
5)     print("Biggest Number is:",n1)
6) elif n2>n3:
7)     print("Biggest Number is:",n2)
8) else :
9)     print("Biggest Number is:",n3)
10)
11) D:\Python_classes>py test.py
12) Enter First Number:10
13) Enter Second Number:20
14) Enter Third Number:30
15) Biggest Number is: 30
16)
17) D:\Python_classes>py test.py
18) Enter First Number:10
```

Q. Write a program to find smallest of given 2 numbers?
Q. Write a program to find smallest of given 3 numbers?
Q. Write a program to check whether the given number is even or odd?
Q. Write a program to check whether the given number is in between 1 and 100?

```
1) n=int(input("Enter Number:"))
2) if n>=1 and n<=10 :
3)     print("The number",n,"is in between 1 to 10")
4) else:
5)     print("The number",n,"is not in between 1 to 10")
```

Q. Write a program to take a single digit number from the key board and print is value in English word?

```
1) 0==>ZERO
2) 1 ==>ONE
3)
4) n=int(input("Enter a digit from o to 9:"))
5) if n==0 :
6)     print("ZERO")
7) elif n==1:
8)     print("ONE")
9) elif n==2:
10)    print("TWO")
11) elif n==3:
12)    print("THREE")
13) elif n==4:
14)    print("FOUR")
15) elif n==5:
16)    print("FIVE")
17) elif n==6:
18)    print("SIX")
19) elif n==7:
20)    print("SEVEN")
21) elif n==8:
22)    print("EIGHT")
23) elif n==9:
24)    print("NINE")
25) else:
26)    print("PLEASE ENTER A DIGIT FROM 0 TO 9")
```

II. Iterative Statements

If we want to execute a group of statements multiple times then we should go for Iterative statements.

Python supports 2 types of iterative statements.

1. for loop
2. while loop

1) for loop:

If we want to execute some action for every element present in some sequence(it may be string or collection)then we should go for: for loop.

Syntax:

for x in sequence
  :body

where sequence can be string or any collection.
Body will be executed for every element present in the

sequence.**Eg 1:** To print characters present in the given string

```
1)  s="Sunny Leone"
2)  for x in s :
3)      print(x)
4)
5)  Output
6)  S
7)  u
8)  n
9)  n
10) y
11)
12) L
13) e
14) o
15) n
16) e
```

Eg 2: To print characters present in string index wise:

```
1) s=input("Enter some String: ")
2) i=0
3) for x in s :
4)     print("The character present at ",i,"index is :",x)
5)     i=i+1
6)
7)
8)   D:\Python_classes>py test.py
9) Enter some String: Sunny Leone
10) The character present at 0 index is : S
11) The character present at 1 index is : u
12) The character present at 2 index is : n
13) The character present at 3 index is : n
14) The character present at 4 index is : y
15) The character present at 5 index is :
16) The character present at 6 index is : L
17) The character present at 7 index is : e
18) The character present at 8 index is : o
19) The character present at 9 index is : n
20) The character present at 10 index is : e
```

Eg 3: To print Hello 10 times

```
1) for x in range(10) :
2)     print("Hello")
```

Eg 4: To display numbers from 0 to 10

```
1)     for x in range(11) :
2)     print(x)
```

Eg 5: To display odd numbers from 0 to 20

```
1)     for x in range(21) :
2)     if (x%2!=0):
3)       print(x)
```

Eg 6: To display numbers from 10 to 1 in descending order

```
1)       for x in range(10,0,-1) :
2)       print(x)
```

Eg 7: **To print sum of numbers presenst inside list**

```
1)        list=eval(input("Enter List:"))
2)     sum=0;
3)     for x in list:
4)        sum=sum+x;
5)     print("The Sum=",sum)
6)
7)  D:\Python_classes>py test.py
8) Enter List:[10,20,30,40]
9)  The Sum= 100
10)
11) D:\Python_classes>py test.py
12) Enter List:[45,67]
13)   The Sum= 112
```

2) while loop:

If we want to execute a group of statements iteratively until some condition false, then we should go for while loop.

Syntax:

```
while condition
   :body
```

Eg: To print numbers from 1 to 10 by using while loop

```
1)       x=1
2)       while x <=10:
3)       print(x)
4)       x=x+1
```

Eg: To display the sum of first n numbers

```
1)  n=int(input("Enter number:"))
2) sum=0
3) i=1
4) while i<=n:
5)    sum=sum+i
6)    i=i+1
7)  print("The sum of first",n,"numbers is :",sum)
```

Eg: write a program to prompt user to enter some name until entering Durga

```
1) name=""
2) while name!="durga":
3)    name=input("Enter Name:")
4) print("Thanks for confirmation")
```

Infinite Loops:

```
1) i=0;
2) while True :
3)    i=i+1;
4)    print("Hello",i)
```

Nested Loops:

Sometimes we can take a loop inside another loop,which are also known as nested loops.

Eg:

```
1) for i in range(4):
2)    for j in range(4):
3)       print("i=",i," j=",j)
4)
5) Output
6) D:\Python_classes>py test.py
7) i= 0  j= 0
8) i= 0  j= 1
9) i= 0  j= 2
10) i= 0  j= 3
11) i= 1  j= 0
12) i= 1  j= 1
13) i= 1  j= 2
14) i= 1  j= 3
15) i= 2  j= 0
16) i= 2  j= 1
17) i= 2  j= 2
18) i= 2  j= 3
19) i= 3  j= 0
20) i= 3  j= 1
21) i= 3  j= 2
22) i= 3  j= 3
```

Q. Write a program to dispaly *'s in Right angled triangled form

```
1)  *
2)  * *
3)  * * *
4)  * * * *
5)  * * * * *
6)  * * * * * *
7)  * * * * * * *
8)
9)  n = int(input("Enter number of rows:"))
10) for i in range(1,n+1):
11)    for j in range(1,i+1):
12)        print("*",end=" ")
13)    print()
```

Alternative way:

```
1) n = int(input("Enter number of rows:"))
2) for i in range(1,n+1):
3)     print("* " * i)
```

Q. Write a program to display *'s in pyramid style(also known as equivalent triangle)

```
1)        *
2)       * *
3)      * * *
4)     * * * *
5)    * * * * *
6)   * * * * * *
7)  * * * * * * *
8)
9)  n = int(input("Enter number of rows:"))
10) for i in range(1,n+1):
11)    print(" " * (n-i),end="")
12)    print("* "*i)
```

III. **Transfer Statements**

1) break:

We can use break statement inside loops to break loop execution based on some condition.

Eg:

```
1)  for i in range(10):
2)    if i==7:
3)      print("processing is enough..plz break")
4)      break
5)    print(i)
6)
7) D:\Python_classes>py test.py
8) 0
9) 1
10) 2
11) 3
12) 4
13) 5
14) 6
15) processing is enough..plz break
```

Eg:

```
1)  cart=[10,20,600,60,70]
2) for item in cart:
3)    if item>500:
4)      print("To place this order insurence must be required")
5)      break
6)    print(item)
7)
8) D:\Python_classes>py test.py
9) 10
10) 20
11) To place this order insurence must be required
```

2) continue:

We can use continue statement to skip current iteration and continue next iteration.

Eg 1: To print odd numbers in the range 0 to 9

```
1) for i in range(10):
2)    if i%2==0:
3)        continue
4)    print(i)
5)
6) D:\Python_classes>py test.py
7) 1
8) 3
9) 5
10) 7
11) 9
```

Eg 2:

```
1) cart=[10,20,500,700,50,60]
2) for item in cart:
3)    if item>=500:
4)        print("We cannot process this item :",item)
5)        continue
6)    print(item)
7)
8) Output
9) D:\Python_classes>py test.py
10) 10
11) 20
12) We cannot process this item : 500
13) We cannot process this item : 700
14) 50
15) 60
```

Eg 3:

```
1) numbers=[10,20,0,5,0,30]
2) for n in numbers:
3)    if n==0:
4)        print("Hey how we can divide with zero..just skipping")
5)        continue
6)    print("100/{} = {}".format(n,100/n))
7)
```

```
8)  Output
9)
10) 100/10 = 10.0
11) 100/20 = 5.0
12) Hey how we can divide with zero..just skipping
13) 100/5 = 20.0
14) Hey how we can divide with zero..just skipping
15) 100/30 = 3.3333333333333335
```

loops with else block:

Inside loop execution, if break statement not executed ,then only else part will be executed.

else means loop without break

Eg:

```
1)  cart=[10,20,30,40,50]
2)  for item in cart:
3)      if item>=500:
4)          print("We cannot process this order")
5)          break
6)      print(item)
7)  else:
8)      print("Congrats ...all items processed successfully")
9)
10) Output
11) 10
12) 20
13) 30
14) 40
15) 50
16) Congrats ...all items processed successfully
```

Eg:

```
1)  cart=[10,20,600,30,40,50]
2)  for item in cart:
3)      if item>=500:
4)          print("We cannot process this order")
5)          break
6)      print(item)
7)  else:
8)      print("Congrats ...all items processed successfully")
```

```
 9)
10) Output
11) D:\Python_classes>py test.py
12) 10
13) 20
14) We cannot process this order
```

Q. What is the difference between for loop and while loop in Python?

We can use loops to repeat code execution
Repeat code for every item in sequence ==>for loop
Repeat code as long as condition is true ==>while loop

Q. How to exit from the loop?by using break statement

Q. How to skip some iterations inside loop?by using continue statement.

Q. When else part will be executed wrt loops?
If loop executed without break

3) pass statement:

pass is a keyword in Python.

In our programming syntactically if block is required which won't do anything then we candefine that empty block with pass keyword.

pass
   |- It is an empty statement
   |- It is null statement
   |- It won't do

anythingEg:

if True:
SyntaxError: unexpected EOF while parsing

if True: pass
==>valid

def m1():
SyntaxError: unexpected EOF while parsing

def m1(): pass

use case of pass:

Sometimes in the parent class we have to declare a function with empty body and child class responsible to provide proper implementation. Such type of empty body we can define by using pass keyword. (It is something like abstract method in java)

Eg:
 def m1():

passEg:

```
1) for i in range(100):
2)    if i%9==0:
3)       print(i)
4)    else:pass
5)
6) D:\Python_classes>py test.py
7) 0
8) 9
9) 18
10) 27
11) 36
12) 45
13) 54
14) 63
15) 72
16) 81
17) 90
18) 99
```

del statement:

del is a keyword in Python.

After using a variable, it is highly recommended to delete that variable if it is no longer required,so that the corresponding object is eligible for Garbage Collection.
We can delete variable by using del keyword.

Eg:

```
1) x=10
2) print(x)
3) del x
```

After deleting a variable, we cannot access that variable otherwise we will get

NameError.**Eg:**

```
1) x=10
2) del x
3) print(x)
```

NameError: name 'x' is not defined.

Note:
We can delete variables which are pointing to immutable objects.But we cannot deletethe elements present inside immutable object.

Eg:

```
1) s="durga"
2) print(s)
3) del  s==>valid
4) del s[0] ==>TypeError: 'str' object doesn't support item deletion
```

Difference between del and None:

In the case del, the variable will be removed and we cannot access that variable(unbind operation)

```
1) s="durga"
2)  del s
3)  print(s)     ==>NameError: name 's' is not defined.
```

But in the case of None assignment the variable won't be removed but the corresponding object is eligible for Garbage Collection(re bind operation). Hence after assigning with None value, we can access that variable.

```
1)  s="durga"
2)  s=None
3)  print(s)   # None
```

String Data Type

The most commonly used object in any project and in any programming, language is String only.Hence, we should aware complete information about String data type.

What is String?

Any sequence of characters within either single quotes or double quotes is considered as a String.

Syntax:
s='durga'
s="durga
"

Note: In most of other languages like C, C++,Java, a single character with in single quotes is treatedas char data type value. But in Python we are not having char data type. Hence it is treated as String only.

Eg:
>>> ch='a'
>>> type(ch)
<class 'str'>

How to define multi-line String literals:

We can define multi-line String literals by using triple single or double quotes.

Eg:
>>>
s='''durga
software
solutions'''

We can also use triple quotes to use single quotes or double quotes as symbol inside String literal.

Eg:
s='This is ' single quote symbol'
==>invalids='This is \' single quote
symbol' ==>valid s="This is ' single quote
symbol"====>valids='This is " double
quotes symbol' ==>valid
s='The "Python Notes" by 'durga' is very helpful'
==>invalid s="The "Python Notes" by 'durga' is very
helpful"==>invalid s='The \"Python Notes\" by \'durga\' is
very helpful' ==>valids='''The "Python Notes" by 'durga'
is very helpful''' ==>valid

How to access characters of a String:

We can access characters of a string by using the following ways.

1. By using index
2. By using slice operator

1. By using index:

Python supports both +ve and -ve index.
+ve index means left to right(Forward direction)
-ve index means right to left(Backward direction)

Eg:
s='durga

'

diagram

Eg:
```
>>> s='durga'
>>> s[0]
'd'
>>> s[4]
'a'
>>> s[-1]
'a'
>>> s[10]
IndexError: string index out of range
```

Note: If we are trying to access characters of a string with out of range index then we will get error saying : IndexError

Q. Write a program to accept some string from the keyboard and display its characters by index wise(both positive and nEgative index)

test.py:

```
1)  s=input("Enter Some String:")
2)  i=0
3)  for x in s:
4)      print("The character present at positive index {} and at nEgative index {}  is {}".format(i,i
    -len(s),x))
5)      i=i+1
```

Output:
D:\python_classes>py test.py
Enter Some String:durga

The character present at positive index 0 and at nEgative index -5 is d The character present at positive index 1 and at nEgative index -4 is u The character present at positive index 2 and at nEgative index -3 is r The character present at positive index 3 and at nEgative index -2 is g The character present at positive index 4 and at nEgative index -1 is a

2. Accessing characters by using slice operator:

Syntax: s[bEginindex:endindex:step]

bEginindex:From where we have to consider slice(substring)
endindex: We have to terminate the slice(substring) at endindex-
1step: incremented value

Note: If we are not specifying bEgin index then it will consider from bEginning of the string.If we are not specifying end index then it will consider up to end of the string
The default value for step is 1

Eg:

```
1)  >>> s="Learning Python is very very easy!!!"
2) >>> s[1:7:1]
3)  'earnin'
4) >>> s[1:7]
5)  'earnin'
6) >>> s[1:7:2]
7)  'eri'
8) >>> s[:7]
9)  'Learnin'
10) >>> s[7:]
11) 'g Python is very very easy!!!'
12) >>> s[::]
13) 'Learning Python is very very easy!!!'
14) >>> s[:]
15) 'Learning Python is very very easy!!!'
16) >>> s[::-1]
17) '!!!ysae yrev yrev si nohtyP gninraeL'
```

Behaviour of slice operator:

s[bEgin:end:step]

step value can be either +ve or –ve

if +ve then it should be forward direction(left to right) and we have to consider bEgin to

end-1 if -ve then it should be backward direction(right to left) and we have to consider bEgin

to end+1

***Note:
In the backward direction if end value is -1 then result is always empty.In the forward direction if end value is 0 then result is always empty.

In forward direction:

default value for bEgin: 0
default value for end: length of stringdefault value for step: +1

In backward direction:

default value for bEgin: -1
default value for end: -(length of string+1)

Note: **Either forward or backward direction, we can take both +ve and -ve values for bEgin andend index.**

Mathematical Operators for String:

We can apply the following mathematical operators for Strings.

1. + operator for concatenation
2. * operator for repetition

print("durga"+"soft")
#durgasoftprint("durga"*2)
#durgadurga

Note:
1. To use + operator for Strings, compulsory both arguments should be str type

2. To use * operator for Strings, compulsory one argument should be str and other argumentshould be int

len() in-built function:

 We can use len() function to find the number of characters present in the string.

 Eg:
 s='durga'
 print(len(s))
 #5

Q. Write a program to access each character of string in forward and backward directionby using while loop?

```
1)  s="Learning Python is very easy !!!"
2)  n=len(s)
3)  i=0
4)  print("Forward direction")
5)  while i<n:
6)      print(s[i],end=' ')
7)      i +=1
8)  print("Backward direction")
9)  i=-1
10) while i>=-n:
11)     print(s[i],end=' ')
12)     i=i-1
```

Alternative ways:

```
1)  s="Learning Python is very easy !!!"
2)  print("Forward direction")
3)  for i in s:
4)      print(i,end=' ')
5)
6)  print("Forward direction")
7)  for i in s[::]:
8)      print(i,end=' ')
9)
10) print("Backward direction")
11) for i in s[::-1]:
12)     print(i,end=' ')
```

Checking Membership:

We can check whether the character or string is the member of another string or not by using inand not in operators

```
s='durga'
print('d' in s)
#Trueprint('z' in
s) #False
```

Program:

```
1)  s=input("Enter main string:")
2)  subs=input("Enter sub string:")
3)  if subs in s:
4)      print(subs,"is found in main string")
5)  else:
```

```
6)    print(subs,"is not found in main string")
```

Output:
D:\python_classes>py test.py
Enter main
string:durgasoftwaresolutionsEnter sub
string:durga
durga is found in main string

D:\python_classes>py test.py
Enter main
string:durgasoftwaresolutionsEnter sub
string:python
python is not found in main string

Comparison of Strings:

We can use comparison operators (<,<=,>,>=) and equality operators(==,!=) for strings.

Comparison will be performed based on alphabetical order.

Eg:

```
1)  s1=input("Enter first string:")
2)  s2=input("Enter Second string:")
3)  if s1==s2:
4)      print("Both strings are equal")
5)  elif s1<s2:
6)      print("First String is less than Second String")
7)  else:
8)      print("First String is greater than Second String")
```

Output:
D:\python_classes>py test.py
Enter first string:durga
Enter Second
string:durgaBoth strings
are equal

D:\python_classes>py test.py
Enter first string:durga
Enter Second string:ravi
First String is less than Second String

D:\python_classes>py test.py
Enter first string:durga
Enter Second string:anil
First String is greater than Second String

Removing spaces from the string:

We can use the following 3 methods

1. rstrip()===>To remove spaces at right hand side
2. lstrip()===>To remove spaces at left hand side
3. strip() ==>To remove spaces both sides

Eg:

```python
1)  city=input("Enter your city Name:")
2)  scity=city.strip()
3)  if scity=='Hyderabad':
4)      print("Hello Hyderbadi..Adab")
5)  elif scity=='Chennai':
6)      print("Hello Madrasi...Vanakkam")
7)  elif scity=="Bangalore":
8)      print("Hello Kannadiga...Shubhodaya")
9)  else:
10)     print("your entered city is invalid")
```

Finding Substrings:

We can use the following 4 methods

For forward direction:

find()
index()

For backward direction:

rfind()
rindex(
)

1. find():

s.find(substring)

Returns index of first occurrence of the given substring. If it is not available then we will get -1

Eg:

```python
1)  s="Learning Python is very easy"
```

```
2)  print(s.find("Python")) #9
3)  print(s.find("Java"))  # -1
4)  print(s.find("r"))#3
5)  print(s.rfind("r"))#21
```

Note: By default find() method can search total string. We can also specify the boundaries to search.

s.find(substring,bEgin,end)

It will always search from bEgin index to end-1 index

Eg:

```
1)  s="durgaravipavanshiva"
2)  print(s.find('a'))#4
3)  print(s.find('a',7,15))#10
4)  print(s.find('z',7,15))#-1
```

index() method:

index() method is exactly same as find() method except that if the specified substring is notavailable then we will get ValueError.

Eg:

```
1)  s=input("Enter main string:")
2)  subs=input("Enter sub string:")
3)  try:
4)      n=s.index(subs)
5)  except ValueError:
6)      print("substring not found")
7)  else:
8)      print("substring found")
```

Output:
D:\python_classes>py test.py
Enter main string:learning python is very
easyEnter sub string:python
substring found

D:\python_classes>py test.py
Enter main string:learning python is very
easyEnter sub string:java
substring not found

Q. Program to display all positions of substring in a given main string

```python
1)  s=input("Enter main string:")
2)  subs=input("Enter sub string:")
3)  flag=False
4)  pos=-1
5)  n=len(s)
6)  while True:
7)      pos=s.find(subs,pos+1,n)
8)      if pos==-1:
9)          break
10)     print("Found at position",pos)
11)     flag=True
12) if flag==False:
13)     print("Not Found")
```

Output:

D:\python_classes>py test.py
Enter   main
string:abbababababacdefgEnter sub
string:a
Found at position 0
Found at position 3
Found at position 5
Found at position 7
Found at position 9
Found   at   position
11

D:\python_classes>py test.py
Enter main
string:abbababababacdefgEnter sub
string:bb
Found at position 1

Counting substring in the given String:

We can find the number of occurrences of substring present in the given string by using count() method.

1. s.count(substring) ==> It will search through out the string
2. s.count(substring, bEgin, end) ===> It will search from bEgin index to end-1 index

Eg:

```python
1)  s="abcabcabcabcadda"
2)  print(s.count('a'))
3)  print(s.count('ab'))
4)  print(s.count('a',3,7))
```

Output:
6
4
2

Replacing a string with another string:

s.replace(oldstring,newstring)

inside s, every occurrence of oldstring will be replaced with newstring.

Eg1:
s="Learning Python is very
difficult"
s1=s.replace("difficult","easy")
print(s1)

Output:
Learning Python is very easy

Eg2: All occurrences will be replaced

s="ababababababab
"
s1=s.replace("a","b
")print(s1)

Output: bbbbbbbbbbbbbb

Q. String objects are immutable then how we can change the content byusing replace() method.

Once we creates string object, we cannot change the content.This non changeable behaviour is nothing but immutability. If we are trying to change the content by using any method, then withthose changes a new object will be created and changes won't be happend in existing object.

Hence with replace() method also a new object got created but existing object won't be changed.

Eg:
s="abab"
s1=s.replace("a","b")
print(s,"is available at
:",id(s))
print(s1,"is available at :",id(s1))

Output:
abab is available at :
4568672bbbb is available at
: 4568704

In the above example, original object is available and we can see new object which was createdbecause of replace() method.

Splitting of Strings:

We can split the given string according to specified seperator by using split() method.

`l=s.split(seperator)`

The default seperator is space. The return type of split() method is List

Eg1:

```
1) s="durga software solutions"
2) l=s.split()
3) for x in l:
4)     print(x)
```

Output:
durga
software
solutions

Eg2:

```
1) s="22-02-2018"
2) l=s.split('-')
3) for x in l:
4)     print(x)
```

Output:
22
02
2018

Joining of Strings:

We can join a group of strings(list or tuple) wrt the given

seperator.s=seperator.join(group of strings)

Eg:
t=('sunny','bunny','chinny
')s='-'.join(t)
print(s)

Output: sunny-bunny-chinny

Eg2:
```
l=['hyderabad','singapore','london','dubai']
s=':'.join(l)
print(s)
```

hyderabad:singapore:london:dubai

Changing case of a String:

We can change case of a string by using the following 4 methods.

1. upper()===>To convert all characters to upper case
2. lower() ===>To convert all characters to lower case
3. swapcase()===>converts all lower case characters to upper case and all upper case characters tolower case
4. title() ===>To convert all character to title case. i.e first character in every word should be uppercase and all remaining characters should be in lower case.
 5. capitalize() ==>Only first character will be converted to upper case and all remaining characterscan be converted to lower case

Eg:
```
s='learning Python is very
Easy'print(s.upper())
print(s.lower())
print(s.swapcase()
)print(s.title())
print(s.capitalize()
)
```

Output:
LEARNING PYTHON IS VERY EASY
learning python is very easy
LEARNING pYTHON IS
VERY eASY
Learning Python Is Very
EasyLearning python is
very easy

Checking starting and ending part of the string:

Python contains the following methods for this purpose

1. s.startswith(substring)
2. s.endswith(substring)

Eg:
```
s='learning Python is very
easy'
print(s.startswith('learning'))
print(s.endswith('learning'))
print(s.endswith('easy'))
```

Output:
True
Fals
e
True

To check type of characters present in a string:

Python contains the following methods for this purpose.

1) <u>isalnum():</u> **Returns True if all characters are alphanumeric(a to z , A to Z ,0 to9)**
2) <u>isalpha():</u> **Returns True if all characters are only alphabet symbols(a to z,A to Z)**
3) <u>isdigit():</u> **Returns True if all characters are digits only(0 to 9)**
4) <u>islower():</u> **Returns True if all characters are lower case alphabet symbols**
5) <u>isupper():</u> **Returns True if all characters are upper case aplhabet symbols**
6) <u>istitle():</u> **Returns True if string is in title case**
7) <u>isspace():</u> **Returns True if string contains only spaces**

<u>Eg:</u>
print('Durga786'.isalnum())   #True
print('durga786'.isalpha())
                              #False
print('durga'.isalpha()) #True
print('durga'.isdigit()) #False
print('786786'.isdigit()) #True
print('abc'.islower())   #True
print('Abc'.islower())
                              #Fals
eprint('abc123'.islower())   #True
print('ABC'.isupper()) #True
print('Learning python is Easy'.istitle())
#False   print('Learning   Python   Is
Easy'.istitle())   #True print('   '.isspace())
#True

<u>Demo Program:</u>

```
1)  s=input("Enter any character:")
2)  if s.isalnum():
3)      print("Alpha Numeric Character")
4)      if s.isalpha():
5)          print("Alphabet character")
6)          if s.islower():
7)              print("Lower case alphabet character")
8)          else:
9)              print("Upper case alphabet character")
10)     else:
11)         print("it is a digit")
12) elif s.isspace():
13)     print("It is space character")
14) else:
```

```
15)   print("Non Space Special Character")
```

D:\python_classes>py test.py

Formatting the Strings:

We can format the strings with variable values by using replacement operator {} and format() method.

Eg:
name='durg
a'
salary=10000
age=48
print("{} 's salary is {} and his age is {}".format(name,salary,age))
print("{0} 's salary is {1} and his age is {2}".format(name,salary,age))
print("{x} 's salary is {y} and his age is {z}".format(z=age,y=salary,x=name))

Output:
durga 's salary is 10000 and his age is 48durga 's salary is 10000 and his age is 48 durga 's salary is 10000 and his age is 48

Important Programs rEgarding String Concept

Q1. Write a program to reverse the given String

input: durga
output:agru
d

1st Way:

s=input("Enter Some
String:")print(s[::-1])

2nd Way:

s=input("Enter Some
String:")
print(''.join(reversed(s)))

3rd Way:

s=input("Enter Some
String:")i=len(s)-1
target=''
while
i>=0:
        target=target+s[i
        ]i=i-1
print(target)

Q2. Program to reverse order of words.

```
1)  input: Learning Python is very Easy
2)  output: Easy Very is Python Learning
3)
4)  s=input("Enter Some String:")
5)  l=s.split()
6)  l1=[]
7)  i=len(l)-1
8)  while i>=0:
9)      l1.append(l[i])
10)     i=i-1
11) output=' '.join(l1)
12) print(output)
```

Output:
Enter Some String:Learning Python is very
easy!!easy!!! very is Python Learning

Q3. Program to reverse internal content of each word.

input: Durga Software Solutions
output: agruD erawtfoS snoituloS

```
1)    s=input("Enter Some String:")
2) l=s.split()
3)  l1=[]
4)  i=0
5)  while i<len(l):
6)     l1.append(l[i][::-1])
7)     i=i+1
8) output=' '.join(l1)
9)  print(output)
```

Q4. Write a program to print characters at odd position and even position for the given String?

1st Way:

```
s=input("Enter Some String:")
print("Characters at Even
Position:",s[0::2])print("Characters at
Odd Position:",s[1::2])
```

2nd Way:

```
1)  s=input("Enter Some String:")
2)  i=0
3)  print("Characters at Even Position:")
4)  while i< len(s):
5)     print(s[i],end=',')
6)     i=i+2
7)  print()
8)  print("Characters at Odd Position:")
9)  i=1
10) while i< len(s):
11)    print(s[i],end=',')
12)    i=i+2
```

Q5. Program to merge characters of 2 strings into a single string by taking characters alternatively.

```
s1="ravi
"
s2="reja
"
```

output: rtaevjia

```
1)  s1=input("Enter First String:")
2)  s2=input("Enter Second String:")
3)  output=''
4)  i,j=0,0
5)  while i<len(s1) or j<len(s2):
6)      if i<len(s1):
7)          output=output+s1[i]
8)          i+=1
9)      if j<len(s2):
10)         output=output+s2[j]
11)         j+=1
12) print(output)
```

Output:

Enter First String:durga
Enter Second
String:ravisoft
druarvgiasoft

Q6. Write a program to sort the characters of the string and first alphabet symbolsfollowed by numeric values

input: B4A1D3
Output: ABD134

```
1)  s=input("Enter Some String:")
2)  s1=s2=output=''
3)  for x in s:
4)      if x.isalpha():
5)          s1=s1+x
6)      else:
7)          s2=s2+x
8)  for x in sorted(s1):
9)      output=output+x
10) for x in sorted(s2):
11)     output=output+x
12) print(output)
```

Q7. Write a program for the following requirement

input: a4b3c2
output:
aaaabbbcc

```
1)  s=input("Enter Some String:")
2)  output=''
3)  for x in s:
4)      if x.isalpha():
5)          output=output+x
6)          previous=x
```

```
7)     else:
8)         output=output+previous*(int(x)-1)
9) print(output)
```

Note: chr(unicode)===>The corresponding character
     ord(character)===>The corresponding unicode value

Q8. Write a program to perform the following activity

input: a4k3b2
output:aeknbd

```
1)  s=input("Enter Some String:")
2) output=''
3) for x in s:
4)     if x.isalpha():
5)         output=output+x
6)         previous=x
7)     else:
8)         output=output+chr(ord(previous)+int(x))
9) print(output)
```

Q9. Write a program to remove duplicate characters from the given input string?

input: ABCDABBCDABBBCCCDDEEEF
output: ABCDEF

```
1)  s=input("Enter Some String:")
2) l=[]
3)  for x in s:
4)     if x not in l:
5)         l.append(x)
6) output=''.join(l)
7)  print(output)
```

Q10. Write a program to find the number of occurrences of each character present in thegiven String?

input: ABCABCABBCDE
output: A-3,B-4,C-3,D-1,E-1

```
1)  s=input("Enter the Some String:")
2) d={}
3)  for x in s:
4)     if x in d.keys():
5)         d[x]=d[x]+1
6)     else:
7)         d[x]=1
```

```
8)  for k,v in d.items():
9)      print("{} = {} Times".format(k,v))
```

Formatting the Strings:

We can format the strings with variable values by using replacement operator {} and format() method.

The main objective of format() method to format string into meaningful output form.

Case- 1: Basic Formatting for default, positional and keyword

argumentsname='durga'
salary=1000
0age=48
print("{} 's salary is {} and his age is {}".format(name,salary,age))
print("{0} 's salary is {1} and his age is {2}".format(name,salary,age))
print("{x} 's salary is {y} and his age is
{z}".format(z=age,y=salary,x=name))

Output:
durga 's salary is 10000 and his age is
48 durga 's salary is 10000 and his age
is 48 durga 's salary is 10000 and his
age is 48

Case-2: Formatting

Numbersd--->Decimal

IntEger
f --->Fixed point number(float).The default precision is 6
b-->Binary
formato >Octal
Format
x-->Hexa Decimal Format(Lower
case)X-->Hexa Decimal
Format(Upper case)

Eg-1:
print("The intEger number is: {}".format(123))
print("The intEger number is: {:d}".format(123))
print("The intEger number is: {:5d}".format(123))
print("The intEger number is: {:05d}".format(123))

Output:
The intEger number is:
123 The intEger number
is: 123   The   intEger
number is: 123
The intEger number is: 00123

Eg-2:

```python
print("The float number is: {}".format(123.4567))
print("The float number is: {:f}".format(123.4567))
```

```
print("The float number is: {:8.3f}".format(123.4567))
print("The float number is: {:08.3f}".format(123.4567))
print("The float number is: {:08.3f}".format(123.45))
print("The float number is:
{:08.3f}".format(786786123.45))
```

Output:
The float number is: 123.4567
The float number is:
123.456700The float number
is: 123.457 The float number
is: 0123.457 The float number
is: 0123.450
The float number is: 786786123.450

Note:
{:08.3f}

Total positions should be minimum 8.
After decimal point exactly 3 digits are allowed.If it is less then 0s will be placed in the lastpositions
If total number is < 8 positions then 0 will be placed in MSBs
If total number is >8 positions then all intEgral digits will be considered.The extra digits we can take only 0

Note: For numbers default alignment is Right Alignment(>)

Eg-3: Print Decimal value in binary, octal and hexadecimal

```
formprint("Binary Form:{0:b}".format(153))
print("Octal Form:{0:o}".format(153))
print("Hexa decimal
Form:{0:x}".format(154))print("Hexa
decimal Form:{0:X}".format(154))
```

Output:
Binary
Form:10011001Octal
Form:231
Hexa decimal
Form:9aHexa
decimal Form:9A

Note: We can represent only int values in binary, octal and hexadecimal and it is not possible forfloat values.

Note:
{:5d} It takes an intEger argument and assigns a minimum width of 5.
{:8.3f} It takes a float argument and assigns a minimum width of 8 including "." and after decimalpoint excatly 3 digits are allowed with round operation if required
{:05d} The blank places can be filled with 0. In this place only 0 allowed.

Case-3: **Number formatting for signed numbers**

While displaying positive numbers,if we want to include + then we have to write

{:+d}   and {:+f}

Using plus for -ve numbers there is no use and for -ve numbers - sign will come

automatically.print("int value with sign:{:+d}".format(123))
print("int value with sign:{:+d}".format(-123))
print("float value with sign:{:+f}".format(123.456))
print("float value with sign:{:+f}".format(-123.456))

Output:
int value with
sign:+123int value with
sign:-123
float value with
sign:+123.456000float value with
sign:-123.456000

Case-4: **Number formatting with alignment**

<,>,^ and = are used for alignment
<==>Left Alignment to the remaining space
^===>Center alignment to the remaining space
>===> Right alignment to the remaining space
=   ===>Forces the signed(+) (-) to the left most

position **Note:** **Default Alignment for numbers is Right**

Alignment.**Ex:**

```
1)  print("{:5d}".format(12))
2) print("{:<5d}".format(12))
3)  print("{:<05d}".format(12))
4) print("{:>5d}".format(12))
5)  print("{:>05d}".format(12))
6) print("{:^5d}".format(12))
7)  print("{:=5d}".format(-12))
8) print("{:^10.3f}".format(12.23456))
9)  print("{:=8.3f}".format(-12.23456))
```

Output:
12
12
12000
12
00012
12
-12

12.235
- 12.235

Case-5: String formatting with format()

Similar to numbers, we can format String values also with format() method.

s.format(string)

Eg:

1) print("{:5d}".format(12))
2) print("{:5}".format("rat"))
3) print("{:>5}".format("rat"))
4) print("{:<5}".format("rat"))
5) print("{:^5}".format("rat"))
6) print("{:*^5}".format("rat")) #Instead of * we can use any character(like +,$,a etc)

Output:
12
ra
t
ra
t
ra
t
ra
t
rat

Note: For numbers default alignment is right where as for strings default alignment is left

Case-6: Truncating Strings with format() method

1) print("{:.3}".format("durgasoftware"))
2) print("{:5.3}".format("durgasoftware"))
3) print("{:>5.3}".format("durgasoftware"))
4) print("{:^5.3}".format("durgasoftware"))
5) print("{:*^5.3}".format("durgasoftware"))

Output:
du
r
du
r
du
r
dur
dur

Case-7: Formatting dictionary members using format()

1) person={'age':48,'name':'durga'}
2) print("{p[name]}'s age is: {p[age]}".format(p=person))

Output:
durga's age is: 48
Note: p is alias name of dictionary
person dictionary we are passing as keyword

argumentMore convinient way is to use **person

Eg:

```
1) person={'age':48,'name':'durga'}
2) print("{name}'s age is: {age}".format(**person))
```

Output:
durga's age is: 48

Case-8: Formatting class members using format()

Eg:

```
1) class Person:
2)     age=48
3)     name="durga"
4) print("{p.name}'s age is :{p.age}".format(p=Person()))
```

Output:
durga's age is :48

Eg:

```
1) class Person:
2)     def __init__(self,name,age):
3)         self.name=name
4)         self.age=age
5) print("{p.name}'s age is :{p.age}".format(p=Person('durga',48)))
6) print("{p.name}'s age is :{p.age}".format(p=Person('Ravi',50)))
```

Note: Here Person object is passed as keyword argument. We can access by using its referencevariable in the template string

Case-9: Dynamic Formatting using format()

```
1) string="{:{fill}{align}{width}}"
2) print(string.format('cat',fill='*',align='^',width=5))
3) print(string.format('cat',fill='*',align='^',width=6))
4) print(string.format('cat',fill='*',align='<',width=6))
5) print(string.format('cat',fill='*',align='>',width=6))
```

Output:
cat
*cat**
cat***
***cat

Case-10: Dynamic Float format template

```
1) num="{:{align}{width}.{precision}f}"
2) print(num.format(123.236,align='<',width=8,precision=2))
3) print(num.format(123.236,align='>',width=8,precision=2))
```

Output:
123.24
123.24

Case-11: Formatting Date values

```
1) import datetime
2) #datetime formatting
3) date=datetime.datetime.now()
4) print("It's now:{:%d/%m/%Y  %H:%M:%S}".format(date))
```

Output: It's now:09/03/2018 12:36:26

Case-12: Formatting complex numbers

```
1) complexNumber=1+2j
2) print("Real Part:{0.real} and Imaginary Part:{0.imag}".format(complexNumber))
```

Output: Real Part:1.0 and Imaginary Part:2.0

List Data Structure

If we want to represent a group of individual objects as a single entity where insertion order preserved and duplicates are allowed, then we should go for List.

insertion order preserved.
duplicate objects are allowed
heterogeneous objects are allowed.
List is dynamic because based on our requirement we can increase the size and decreasethe size.
In List the elements will be placed within square brackets and with comma seperator.

We can differentiate duplicate elements by using index and we can preserve insertion order by using index. Hence index will play very important role.
Python supports both positive and negative indexes. +ve index means from left to right where as negative index means right to left

[10,"A","B",20, 30, 10]

-6	-5	-4	-3	-2	-1
10	A	B	20	30	10
0	1	2	3	4	5

List objects are mutable.i.e we can change the content.

Creation of List Objects:

1. **We can create empty list object as follows...**

```
1) list=[]
2) print(list)
3) print(type(list))
4)
5) []
6) <class 'list'>
```

2. If we know elements already then we can create list as
followslist=[10,20,30,40]

3. With dynamic input:

```
1)  list=eval(input("Enter List:"))
2)  print(list)
3)  print(type(list))
4)
5)   D:\Python_classes>py test.py
6)  Enter List:[10,20,30,40]
7)  [10, 20, 30, 40]
8)  <class 'list'>
```

4. With list() function:

```
1)  l=list(range(0,10,2))
2)  print(l)
3)  print(type(l))
4)
5)  D:\Python_classes>py test.py
6)  [0, 2, 4, 6, 8]
7)  <class 'list'>
```

Eg:

```
1)  s="durga"
2)  l=list(s)
3)  print(l)
4)
5)  D:\Python_classes>py test.py
6)  ['d', 'u', 'r', 'g', 'a']
```

5. with split() function:

```
1)  s="Learning Python is very very easy !!!"
2)  l=s.split()
3)  print(l)
4)  print(type(l))
5)
6)  D:\Python_classes>py test.py
7)  ['Learning', 'Python', 'is', 'very', 'very', 'easy', '!!!']
8)  <class 'list'>
```

Note:

Sometimes we can take list inside another list,such type of lists are called nested lists.
[10,20,[30,40]]

Accessing elements of List:

We can access elements of the list either by using index or by using slice operator(:)
1. By using index:

List follows zero based index. ie index of first element is zero.
List supports both +ve and -ve indexes.
+ve index meant for Left to Right
-ve index meant for Right to

Leftlist=[10,20,30,40]

```
         -4    -3    -2    -1
list →  | 10 | 20 | 30 | 40 |
          0     1     2     3
```

print(list[0]) ==>10
print(list[-1]) ==>40
print(list[10]) ==>IndexError: list index out of range

2. By using slice operator:

Syntax:

list2= list1[start:stop:step]

start ==>it indicates the index where slice has to start
         default value is 0

stop ===>It indicates the index where slice has to end
          default value is max allowed index of list ie length of the list

step ==>increment value
         default value is 1

Eg:

```
1)  n=[1,2,3,4,5,6,7,8,9,10]
2)  print(n[2:7:2])
3)  print(n[4::2])
4)  print(n[3:7])
5)  print(n[8:2:-2])
6)  print(n[4:100])
```

```
7)
8)   Output
9)  D:\Python_classes>py test.py
10) [3, 5, 7]
11) [5, 7, 9]
12) [4, 5, 6, 7]
13) [9, 7, 5]
14) [5, 6, 7, 8, 9, 10]
```

List vs mutability:

Once we creates a List object,we can modify its content. Hence List objects are mutable.

Eg:

```
1)   n=[10,20,30,40]
2)   print(n)
3)   n[1]=777
4)   print(n)
5)
6)   D:\Python_classes>py test.py
7)   [10, 20, 30, 40]
8)   [10, 777, 30, 40]
```

Traversing the elements of List:

The sequential access of each element in the list is called traversal.

1. By using while loop:

```
1)  n=[0,1,2,3,4,5,6,7,8,9,10]
2)  i=0
3)  while i<len(n):
4)      print(n[i])
5)      i=i+1
6)
7) D:\Python_classes>py test.py
8)  0
9)  1
10) 2
11) 3
12) 4
13) 5
14) 6
15) 7
16) 8
17) 9
```

18) **10**

2. By using for loop:

```
1)    n=[0,1,2,3,4,5,6,7,8,9,10]
2)    for n1 in n:
3)        print(n1)
4)
5)    D:\Python_classes>py test.py
6)    0
7)    1
8)    2
9)    3
10)   4
11)   5
12)   6
13)   7
14)   8
15)   9
16)   10
```

3. To display only even numbers:

```
1)    n=[0,1,2,3,4,5,6,7,8,9,10]
2)    for n1 in n:
3)        if n1%2==0:
4)            print(n1)
5)
6)    D:\Python_classes>py test.py
7)    0
8)    2
9)    4
10)   6
11)   8
12)   10
```

4. To display elements by index wise:

```
1)    l=["A","B","C"]
2)    x=len(l)
3)    for i in range(x):
4)        print(l[i],"is available at positive index: ",i,"and at negative index: ",i-x)
5)
6)    Output
7)    D:\Python_classes>py test.py
8)    A is available at positive index:  0 and at negative index:  -3
9)    B is available at positive index:  1 and at negative index:  -2
10)   C is available at positive index:  2 and at negative index:  -1
```

Important functions of List:

I. To get information about list:

1. len():
returns the number of elements present in the list

Eg: n=[10,20,30,40]
print(len(n))==>4

2. count():
It returns the number of occurrences of specified item in the list

```
1) n=[1,2,2,2,2,3,3]
2) print(n.count(1))
3) print(n.count(2))
4) print(n.count(3))
5) print(n.count(4))
6)
7)  Output
8) D:\Python_classes>py test.py
9) 1
10) 4
11) 2
12) 0
```

3. index() function:

returns the index of first occurrence of the specified item.

Eg:

```
1) n=[1,2,2,2,2,3,3]
2) print(n.index(1))     ==>0
3) print(n.index(2))     ==>1
4) print(n.index(3))     ==>5
5) print(n.index(4))     ==>ValueError: 4 is not in list
```

Note: If the specified element not present in the list then we will get ValueError.Hence before index() method we have to check whether item present in the list or not by using inoperator.

print(4 in n)==>False

II.Manipulating elements of List:

1. append() function:

We can use append() function to add item at the end of the list.

Eg:

```
1)  list=[]
2)  list.append("A")
3)  list.append("B")
4)  list.append("C")
5)  print(list)
6)
7)  D:\Python_classes>py test.py
8)  ['A', 'B', 'C']
```

Eg: To add all elements to list upto 100 which are divisible by 10

```
1)  list=[]
2)  for i in range(101):
3)      if i%10==0:
4)          list.append(i)
5)  print(list)
6)
7)
8)  D:\Python_classes>py test.py
9)  [0, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100]
```

2. insert() function:

To insert item at specified index position

```
1)  n=[1,2,3,4,5]
2)  n.insert(1,888)
3)  print(n)
4)
5)  D:\Python_classes>py test.py
6)  [1, 888, 2, 3, 4, 5]
```

Eg:

```
1)  n=[1,2,3,4,5]
2)  n.insert(10,777)
3)  n.insert(-10,999)
4)  print(n)
5)
```

<u>Note:</u> If the specified index is greater than max index then element will be inserted at lastposition. If the specified index is smaller than min index then element will be inserted at first position.

Differences between append() and insert()

append()	insert()
In List when we add any element it willcome in last i.e. it will be last element.	In List we can insert any element inparticular index number

3. extend() function:

To add all items of one list to another list

l1.extend(l2)
  all items present in l2 will be added to

l1Eg:

```
1)  order1=["Chicken","Mutton","Fish"]
2) order2=["RC","KF","FO"]
3)  order1.extend(order2)
4) print(order1)
5)
6) D:\Python_classes>py test.py
7)  ['Chicken', 'Mutton', 'Fish', 'RC', 'KF', 'FO']
```

<u>Eg:</u>

```
1)  order=["Chicken","Mutton","Fish"]
2)  order.extend("Mushroom")
3)  print(order)
4)
5)  D:\Python_classes>py test.py
6)  ['Chicken', 'Mutton', 'Fish', 'M', 'u', 's', 'h', 'r', 'o', 'o', 'm']
```

4. remove() function:

We can use this function to remove specified item from the list.If the item presentmultiple times then only first occurrence will be removed.

```
1)  n=[10,20,10,30]
2)  n.remove(10)
3)  print(n)
4)
5)  D:\Python_classes>py test.py
6)  [20, 10, 30]
```

If the specified item not present in list then we will get ValueError

```
1)  n=[10,20,10,30]
2)  n.remove(40)
3)  print(n)
4)
5)  ValueError: list.remove(x): x not in list
```

<u>Note:</u> Hence before using remove() method first we have to check specified element present in the list or not by using in operator.

5. pop() function:

It removes and returns the last element of the list.
This is only function which manipulates list and returns some

element.<u>Eg:</u>

```
1)  n=[10,20,30,40]
2)  print(n.pop())
3)  print(n.pop())
4)  print(n)
5)
6)  D:\Python_classes>py test.py
7)  40
8)  30
9)  [10, 20]
```

If the list is empty then pop() function raises

IndexError<u>Eg:</u>

```
1)  n=[]
2)  print(n.pop())  ==>   IndexError: pop from empty list
```

Note:

1. pop() is the only function which manipulates the list and returns some value
2. In general we can use append() and pop() functions to implement stack data structureby using list, which follows LIFO(Last In First Out) order.

In general we can use pop() function to remove last element of the list. But we can use to remove elements based on index.

n.pop(index)===>To remove and return element present at specified index.
n.pop()==>To remove and return last element of the list

```
1)  n=[10,20,30,40,50,60]
2)  print(n.pop())  #60
3)  print(n.pop(1))   #20
4)  print(n.pop(10))  ==>IndexError: pop index out of range
```

Differences between remove() and pop()

remove()	pop()
1) We can use to remove special element from the List.	1) We can use to remove last element from the List.
2) It can't return any value.	2) It returned removed element.
3) If special element not available then weget VALUE ERROR.	3) If List is empty then we get Error.

Note:

List objects are dynamic. i.e based on our requirement we can increase and decrease the size.

append(),insert() ,extend() ===>for increasing the size/growable nature
remove(), pop() ======>for decreasing the size /shrinking nature

III.   Ordering elements of List:

1. reverse():

We can use to reverse() order of elements of list.

```
1)  n=[10,20,30,40]
2)  n.reverse()
3)  print(n)
4)
5)  D:\Python_classes>py test.py
6)  [40, 30, 20, 10]
```

2. sort() function:

In list by default insertion order is preserved. If want to sort the elements of list accordingto default natural sorting order then we should go for sort() method.

For numbers ==>default natural sorting order is Ascending Order
For Strings ==>   default natural sorting order is Alphabetical Order

```
1)  n=[20,5,15,10,0]
2)  n.sort()
3)   print(n)      #[0,5,10,15,20]
4)
5)  s=["Dog","Banana","Cat","Apple"]
6)  s.sort()
7)   print(s)  #['Apple','Banana','Cat','Dog']
```

Note: To use sort() function, compulsory list should contain only homogeneous elements. otherwise we will get TypeError

Eg:

```
1)  n=[20,10,"A","B"]
2)  n.sort()
3)  print(n)
4)
5)   TypeError: '<' not supported between instances of 'str' and 'int'
```

Note: In Python 2 if List contains both numbers and Strings then sort() function first sort numbers followed by strings

```
1)  n=[20,"B",10,"A"]
2)  n.sort()
```

```
3) print(n)# [10,20,'A','B']
```

But in Python 3 it is invalid.

To sort in reverse of default natural sorting order:

We can sort according to reverse of default natural sorting order by using reverse=True argument.
Eg:

```
1. n=[40,10,30,20]
2. n.sort()
3. print(n) ==>[10,20,30,40]
4. n.sort(reverse=True)
5. print(n) ===>[40,30,20,10]
6. n.sort(reverse=False)
7. print(n) ==>[10,20,30,40]
```

Aliasing and Cloning of List objects:

The process of giving another reference variable to the existing list is called aliasing.

Eg:

```
1) x=[10,20,30,40]
2) y=x
3) print(id(x))
4) print(id(y))
```

The problem in this approach is by using one reference variable if we are changing content,then those changes will be reflected to the other reference variable.

```
1) x=[10,20,30,40]
2) y=x
3) y[1]=777
4) print(x) ==>[10,777,30,40]
```

To overcome this problem we should go for cloning.
The process of creating exactly duplicate independent object is called cloning.

We can implement cloning by using slice operator or by using copy() function

1. By using slice operator:

```
1) x=[10,20,30,40]
2) y=x[:]
3) y[1]=777
4) print(x) ==>[10,20,30,40]
5) print(y) ==>[10,777,30,40]
```

2. By using copy() function:

```
1) x=[10,20,30,40]
2) y=x.copy()
3) y[1]=777
4) print(x) ==>[10,20,30,40]
5) print(y) ==>[10,777,30,40]
```

Q. Difference between = operator and copy() function

= operator meant for aliasing
copy() function meant for
cloning

Using Mathematical operators for List Objects:

We can use + and * operators for List objects.

1. Concatenation operator(+):

We can use + to concatenate 2 lists into a single list

```
1)  a=[10,20,30]
2)  b=[40,50,60]
3)  c=a+b
4)  print(c) ==>[10,20,30,40,50,60]
```

Note: To use + operator compulsory both arguments should be list objects,otherwise we will get TypeError.

Eg:

```
c=a+40        ==>TypeError: can only concatenate list (not "int") to
listc=a+[40]  ==>valid
```

2. Repetition Operator(*):

We can use repetition operator * to repeat elements of list specified number of times

Eg:

```
1)  x=[10,20,30]
2)  y=x*3
3)  print(y)==>[10,20,30,10,20,30,10,20,30]
```

Comparing List objects

We can use comparison operators for List

objects.**Eg:**

```
1.  x=["Dog","Cat","Rat"]
2.  y=["Dog","Cat","Rat"]
3.  z=["DOG","CAT","RAT"]
4.  print(x==y)  True
5.  print(x==z)  False
6.  print(x != z)   True
```

Note:

Whenever we are using comparison operators(==,!=) for List objects then the followingshould be considered
  1. The number of elements
  2. The order of elements
  3. The content of elements (case sensitive)

Note: When ever we are using relatational operators(<,<=,>,>=) between List objects,onlyfirst element comparison will be performed.

Eg:

```
1.  x=[50,20,30]
2.  y=[40,50,60,100,200]
3.  print(x>y)  True
4.  print(x>=y)  True
5.   print(x<y)  False
6.  print(x<=y)  False
```

Eg:

```
1.  x=["Dog","Cat","Rat"]
2.  y=["Rat","Cat","Dog"]
3.  print(x>y)  False
4.  print(x>=y) False
5.  print(x<y)   True
6.  print(x<=y)  True
```

Membership operators:

We can check whether element is a member of the list or not by using memebership operators.

in operator
not in
operator

Eg:

```
1.  n=[10,20,30,40]
2.  print (10 in n)
3.   print (10 not in n)
4.  print (50 in n)
5.   print (50 not in n)
6.
7.  Output
```

8. **True**
9. **False**
10. **False**
11. **True**

clear() function:

We can use clear() function to remove all elements of List.

Eg:

```
1.  n=[10,20,30,40]
2.  print(n)
3.  n.clear()
4.  print(n)
5.
6.  Output
7.  D:\Python_classes>py test.py
8.  [10, 20, 30, 40]
9.  []
```

Nested Lists:

Sometimes we can take one list inside another list. Such type of lists are called nestedlists.

Eg:

```
1.  n=[10,20,[30,40]]
2.  print(n)
3.  print(n[0])
4.  print(n[2])
5.  print(n[2][0])
6.  print(n[2][1])
7.
8.  Output
9.  D:\Python_classes>py test.py
10. [10, 20, [30, 40]]
11. 10
12. [30, 40]
13. 30
14. 40
```

Note: We can access nested list elements by using index just like accessing multi dimensional array elements.

Nested List as Matrix:

In Python we can represent matrix by using nested lists.

```
1)  n=[[10,20,30],[40,50,60],[70,80,90]]
2)  print(n)
3)  print("Elements by Row wise:")
4)  for r in n:
5)      print(r)
6)  print("Elements by Matrix style:")
7)  for i in range(len(n)):
8)      for j in range(len(n[i])):
9)          print(n[i][j],end=' ')
10)     print()
11)
12) Output
13) D:\Python_classes>py test.py
14) [[10, 20, 30], [40, 50, 60], [70, 80, 90]]
15) Elements by Row wise:
16) [10, 20, 30]
17) [40, 50, 60]
18) [70, 80, 90]
19) Elements by Matrix style:
20) 10 20 30
21) 40 50 60
22) 70 80 90
```

List Comprehensions:

It is very easy and compact way of creating list objects from any iterable objects(like list,tuple,dictionary,range etc) based on some condition.

Syntax:
list=[expression for item in list if

condition]Eg:

```
1)  s=[ x*x for x in range(1,11)]
2)  print(s)
3)  v=[2**x  for x in range(1,6)]
4)  print(v)
5)  m=[x for x in s if x%2==0]
6)  print(m)
7)
8)  Output
9)  D:\Python_classes>py test.py
10) [1, 4, 9, 16, 25, 36, 49, 64, 81, 100]
```

11) [2, 4, 8, 16, 32]
12) [4, 16, 36, 64, 100]

Eg:

```
1) words=["Balaiah","Nag","Venkatesh","Chiranjeevi"]
2) l=[w[0] for w in words]
3) print(l)
4)
5) Output['B', 'N', 'V', 'C']
```

Eg:

```
1) num1=[10,20,30,40]
2) num2=[30,40,50,60]
3) num3=[ i for i in num1 if i not in num2]
4) print(num3)   [10,20]
5)
6) common elements present in num1 and num2
7) num4=[i for i in num1 if i in num2]
8) print(num4)   [30, 40]
```

Eg:

```
1) words="the quick brown fox jumps over the lazy dog".split()
2) print(words)
3) l=[[w.upper(),len(w)]    for w in words]
4) print(l)
5)
6) Output
7) ['the', 'quick', 'brown', 'fox', 'jumps', 'over', 'the', 'lazy', 'dog']
8) [['THE', 3], ['QUICK', 5], ['BROWN', 5], ['FOX', 3], ['JUMPS', 5], ['OVER', 4],
9) ['THE', 3], ['LAZY', 4], ['DOG', 3]]
```

Q. Write a program to display unique vowels present in the given word?

```
1) vowels=['a','e','i','o','u']
2) word=input("Enter the word to search for vowels: ")
3) found=[]
4) for letter in word:
5)     if letter in vowels:
6)         if letter not in found:
7)             found.append(letter)
8) print(found)
9) print("The number of different vowels present in",word,"is",len(found))
10)
11)
12) D:\Python_classes>py test.py
```

13) **Enter the word to search for vowels: durgasoftwaresolutions**
14) **['u', 'a', 'o', 'e', 'i']**
15) **The number of different vowels present in durgasoftwaresolutions is 5**

list out all functions of list and write a program to use these functions

Tuple Data Structure

1. Tuple is exactly same as List except that it is immutable. i.e once we creates Tupleobject,we cannot perform any changes in that object.
Hence Tuple is Read Only version of List.
2. If our data is fixed and never changes then we should go for Tuple.
3. Insertion Order is preserved
4. Duplicates are allowed
5. Heterogeneous objects are allowed.
6. We can preserve insertion order and we can differentiate duplicate objects by usingindex. Hence index will play very important role in Tuple also.
Tuple support both +ve and -ve index. +ve index means forward direction(from left to right) and -ve index means backward direction(from right to left)
7. We can represent Tuple elements within Parenthesis and with comma seperator.Parenethesis are optional but recommended to use.

Eg:

```
1.  t=10,20,30,40
2.  print(t)
3.  print(type(t))
4.
5.  Output
6.  (10, 20, 30, 40)
7.  <class 'tuple'>
8.
9.    t=()
10. print(type(t)) # tuple
```

Note: We have to take special care about single valued tuple compulsory the value should ends with comma, otherwise it is not treated as tuple.
Eg:

```
1.  t=(10)
2.  print(t)
3.  print(type(t))
4.
5.  Output
6.  10
7.  <class 'int'>
```

Eg:

```
1.  t=(10,)
2.  print(t)
3.  print(type(t))
4.
5.  Output
6.  (10,)
7.  <class 'tuple'>
```

Q. Which of the following are valid tuples?

1. t=()
2. t=10,20,30,40
3. t=10
4. t=10,
5. t=(10)
6. t=(10,)
7.t=(10,20,30,40)

Tuple creation:

1. t=()
   creation of empty tuple

2. t=(10,)
   t=10,
   creation of single valued tuple, parenthesis are optional, should ends with comma

3. t=10,20,30
   t=(10,20,30)
   creation of multi values tuples & parenthesis are optional

4. By using tuple() function:

```
1.  list=[10,20,30]
2.      t=tuple(list)
3.      print(t)
4.
5.      t=tuple(range(10,20,2))
6.      print(t)
```

Accessing elements of tuple:

We can access either by index or by slice operator

1. By using index:

```
1.  t=(10,20,30,40,50,60)
2.  print(t[0]) #10
3.  print(t[-1]) #60
4.  print(t[100])   IndexError: tuple index out of range
```

2. By using slice operator:

```
1.  t=(10,20,30,40,50,60)
2.  print(t[2:5])
3.  print(t[2:100])
4.  print(t[::2])
5.
6.  Output
7.  (30, 40, 50)
8.  (30, 40, 50, 60)
9.  (10, 30, 50)
```

Tuple vs immutability:

Once we creates tuple,we cannot change its content.
Hence tuple objects are immutable.

Eg:
t=(10,20,30,40)
t[1]=70   TypeError: 'tuple' object does not support item assignment

Mathematical operators for tuple:

We can apply + and * operators for tuple

1. Concatenation Operator(+):

```
1.  t1=(10,20,30)
2.  t2=(40,50,60)
3.  t3=t1+t2
4.  print(t3) # (10,20,30,40,50,60)
```

2. Multiplication operator or repetition operator(*)

```
1.  t1=(10,20,30)
2.  t2=t1*3
3.  print(t2) #(10,20,30,10,20,30,10,20,30)
```

Important functions of Tuple:

1. len()
To return number of elements present in the tuple

Eg:
t=(10,20,30,40)
print(len(t)) #4

2. count()
To return number of occurrences of given element in the tuple

Eg:
t=(10,20,10,10,20)
print(t.count(10)) #3

3. index()
returns index of first occurrence of the given element.
If the specified element is not available then we will get ValueError.

Eg:
t=(10,20,10,10,20)
print(t.index(10)) #0
print(t.index(30)) ValueError: tuple.index(x): x not in tuple

4. sorted()
To sort elements based on default natural sorting order

```
1.  t=(40,10,30,20)
2.  t1=sorted(t)
3.  print(t1)
4.  print(t)
5.
6.   Output
7.   [10, 20, 30, 40]
8.   (40, 10, 30, 20)
```

We can sort according to reverse of default natural sorting order as follows

t1=sorted(t,reverse=True)
print(t1) [40, 30, 20, 10]

5. min() and max() functions:

These functions return min and max values according to default natural sorting

order.**Eg:**

```
1.  t=(40,10,30,20)
2.  print(min(t))  #10
3.  print(max(t))  #40
```

6. cmp():

It compares the elements of both tuples.
If both tuples are equal then returns 0
If the first tuple is less than second tuple then it returns -1
If the first tuple is greater than second tuple then it returns

+1**Eg:**

```
1.  t1=(10,20,30)
2.  t2=(40,50,60)
3.  t3=(10,20,30)
4.  print(cmp(t1,t2)) # -1
5.  print(cmp(t1,t3)) # 0
6.  print(cmp(t2,t3)) # +1
```

Note: cmp() function is available only in Python2 but not in Python 3

Tuple Packing and Unpacking:

We can create a tuple by packing a group of variables.

Eg:

a=10
b=2
0
c=30
d=4
0
t=a,b,c,d
print(t) #(10, 20, 30, 40)

Here a,b,c,d are packed into a tuple t. This is nothing but tuple packing.

Tuple unpacking is the reverse process of tuple packing
We can unpack a tuple and assign its values to different

variables**Eg:**

```
1. t=(10,20,30,40)
2. a,b,c,d=t
3. print("a=",a,"b=",b,"c=",c,"d=",d)
4.
5. Output
6. a= 10 b= 20 c= 30 d= 40
```

Note: At the time of tuple unpacking the number of variables and number of valuesshould be same.,otherwise we will get ValueError.

Eg:
t=(10,20,30,40)
a,b,c=t   #ValueError: too many values to unpack (expected 3)

Tuple Comprehension:

Tuple Comprehension is not supported by

 Python.t= (x**2 for x in range(1,6))

Here we are not getting tuple object and we are getting generator object.

```
1.  t= ( x**2  for x in range(1,6))
2. print(type(t))
3.  for x in t:
4.     print(x)
5.
6. Output
7.  D:\Python_classes>py test.py
8. <class 'generator'>
9.  1
10. 4
11. 9
12. 16
13. 25
```

Q. Write a program to take a tuple of numbers from the keyboard and print its sum and average?

```
1.  t=eval(input("Enter Tuple of Numbers:"))
2.  l=len(t)
3.  sum=0
4.  for x in t:
5.     sum=sum+x
6.  print("The Sum=",sum)
7.  print("The Average=",sum/l)
8.
9.  D:\Python_classes>py test.py
10. Enter Tuple of Numbers:(10,20,30,40)
11. The Sum= 100
12. The Average= 25.0
13.
14. D:\Python_classes>py test.py
15. Enter Tuple of Numbers:(100,200,300)
16. The Sum= 600
17. The Average= 200.0
```

Differences between List and Tuple:

List and Tuple are exactly same except small difference: List objects are mutable where as Tuple objects are immutable.

In both cases insertion order is preserved, duplicate objects are allowed, heterogenousobjects are allowed, index and slicing are supported.

List	Tuple
1) List is a Group of Comma separeated Values within Square Brackets and Square Brackets are mandatory. Eg: i = [10, 20, 30, 40]	1) Tuple is a Group of Comma separeated Values within Parenthesis and Parenthesis are optional. Eg: t = (10, 20, 30, 40) t = 10, 20, 30, 40
2) List Objects are Mutable i.e. once we creates List Object we can perform any changes in that Object. Eg: i[1] = 70	2) Tuple Objeccts are Immutable i.e. once we creates Tuple Object we cannot change its content. t[1] = 70 □ ValueError: tuple object does not support item assignment.
3) If the Content is not fixed and keep on changing then we should go for List.	3) If the content is fixed and never changes then we should go for Tuple.
4) List Objects can not used as Keys for Dictionries because Keys should be Hashable and Immutable.	4) Tuple Objects can be used as Keys forDictionries because Keys should be Hashable and Immutable.

Set   Data Structure

❖ **If we want to represent a group of unique values as a single entity then we should gofor set.**
❖ **Duplicates are not allowed.**
❖ **Insertion order is not preserved.But we can sort the elements.**
❖ **Indexing and slicing not allowed for the set.**
❖ **Heterogeneous elements are allowed.**
❖ **Set objects are mutable i.e once we creates set object we can perform any changes inthat object based on our requirement.**
❖ **We can represent set elements within curly braces and with comma seperation**
❖ **We can apply mathematical operations like union,intersection,difference etc on setobjects.**

Creation of Set objects:

Eg:

```
1.  s={10,20,30,40}
2.  print(s)
3.  print(type(s))
4.
5.  Output
6.  {40, 10, 20, 30}
7.  <class 'set'>
```

We can create set objects by using set() function

s=set(any sequence)

Eg 1:

```
1.  l = [10,20,30,40,10,20,10]
2.  s=set(l)
3.  print(s) # {40, 10, 20, 30}
```

Eg 2:

```
1.  s=set(range(5))
2.  print(s) #{0, 1, 2, 3, 4}
```

Note: **While creating empty set we have to take special care.**
Compulsory we should use set() function.

s={} ==>It is treated as dictionary but not empty set.

Eg
:
```
1.  s={}
2.  print(s)
3.  print(type(s))
4.
5.  Output
6.  {}
7.  <class 'dict'>
```

Eg
:
```
1.  s=set()
2.  print(s)
3.  print(type(s))
4.
5.  Output
6.  set()
7.  <class 'set'>
```

Important functions of set:

1. add(x):

 Adds item x to the

set**Eg:**

```
1.  s={10,20,30}
2.  s.add(40);
3.  print(s)  #{40, 10, 20, 30}
```

2. update(x,y,z):

To add multiple items to the set.
Arguments are not individual elements and these are Iterable objects like List,range etc.All elements present in the given Iterable objects will be added to the set.

Eg:

```
1.  s={10,20,30}
2.  l=[40,50,60,10]
3.  s.update(l,range(5))
4.  print(s)
```

5.
6. **Output**
7. **{0, 1, 2, 3, 4, 40, 10, 50, 20, 60, 30}**

Q. What is the difference between add() and update() functions in set?

We can use add() to add individual item to the Set,where as we can use update() functionto add multiple items to Set.
add() function can take only one argument where as update() function can take any number of arguments but all arguments should be iterable objects.

Q. Which of the following are valid for set s?

1. **s.add(10)**
2. **s.add(10,20,30)**   **TypeError: add() takes exactly one argument (3 given)**
3. **s.update(10)**   **TypeError: 'int' object is not**
iterable4. s.update(range(1,10,2),range(0,10,2))

3. copy():

**Returns copy of the
set.It is cloned object.**

**s={10,20,30}
s1=s.copy(
)print(s1)**

4. pop():

It removes and returns some random element from the

set.Eg:

1. s={40,10,30,20}
2. print(s)
3. print(s.pop())
4. print(s)
5.
6. Output
7. {40, 10, 20, 30}
8. 40
9. {10, 20, 30}

5. remove(x):

It removes specified element from the set.
If the specified element not present in the Set then we will get KeyError

```
s={40,10,30,20}
s.remove(30)
print(s)        # {40, 10, 20}
s.remove(50)  ==>KeyError: 50
```

6. discard(x):

It removes the specified element from the set.
If the specified element not present in the set then we won't get any error.

```
s={10,20,30}
s.discard(10)
print(s)        ===>{20,
30}s.discard(50)
print(s)        ==>{20, 30}
```

Q. What is the difference between remove() and discard() functions in Set?
Q. Explain differences between pop(),remove() and discard() functionsin Set?

7.clear():

To remove all elements from the Set.

```
1.  s={10,20,30}
2.  print(s)
3.  s.clear()
4.  print(s)
5.
6.  Output
7.  {10, 20, 30}
8.  set()
```

Mathematical operations on the Set:

1.union():

x.union(y) ==>We can use this function to return all elements present in both

setsx.union(y) or   x|y

Eg:
x={10,20,30,40}
y={30,40,50,60}
print(x.union(y))   #{10, 20, 30, 40, 50, 60}
print(x|y)   #{10, 20, 30, 40, 50, 60}

2. intersection():

x.intersection(y) or   x&y

Returns common elements present in both x and

y**Eg:**

x={10,20,30,40}
y={30,40,50,60}
print(x.intersection(y))   #{40, 30}
print(x&y)   #{40, 30}

3. difference():

x.difference(y) or x-y
returns the elements present in x but not in

y**Eg:**

 x={10,20,30,40}
y={30,40,50,60}
print(x.difference(y)) #{10, 20}
print(x-y)   #{10, 20}
print(y-x)   #{50, 60}

4.symmetric_difference():

x.symmetric_difference(y) or x^y

Returns elements present in either x or y but not in both

Eg:

```
x={10,20,30,40}
y={30,40,50,60}
print(x.symmetric_difference(y))    #{10, 50, 20, 60}
print(x^y)      #{10, 50, 20, 60}
```

Membership operators: (in , not in)

Eg:

```
1.   s=set("durga")
2. print(s)
3.  print('d' in s)
4. print('z' in s)
5.
6. Output
7. {'u', 'g', 'r', 'd', 'a'}
8. True
9.  False
```

Set Comprehension:

Set comprehension is possible.

```
s={x*x  for x  in
range(5)}print(s) #{0, 1,
4, 9, 16}
```

```
 s={2**x for x in
range(2,10,2)} print(s) #{16,
256, 64, 4}
```

set objects won't support indexing and slicing:

Eg:
```
s={10,20,30,40}
print(s[0])      ==>TypeError: 'set' object does not support
indexingprint(s[1:3]) ==>TypeError: 'set' object is not
subscriptable
```

Q.Write a program to eliminate duplicates present in the list?

Approach-1:

```
1.  l=eval(input("Enter List of values: "))
2.  s=set(l)
3.  print(s)
4.
5.  Output
6.  D:\Python_classes>py test.py
7.  Enter List of values: [10,20,30,10,20,40]
8.  {40, 10, 20, 30}
```

Approach-2:

```
1.  l=eval(input("Enter List of values: "))
2.  l1=[]
3.  for x in l:
4.      if x not in l1:
5.          l1.append(x)
6.  print(l1)
7.
8.  Output
9.  D:\Python_classes>py test.py
10. Enter List of values: [10,20,30,10,20,40]
11. [10, 20, 30, 40]
```

Q. Write a program to print different vowels present in the given word?

```
1.  w=input("Enter word to search for vowels: ")
2.  s=set(w)
3.  v={'a','e','i','o','u'}
4.  d=s.intersection(v)
5.  print("The different vowel present in",w,"are",d)
6.
7.  Output
8.  D:\Python_classes>py test.py
9.  Enter word to search for vowels: durga
10. The different vowel present in durga are {'u', 'a'}
```

Dictionary Data Structure

We can use List,Tuple and Set to represent a group of individual objects as a single entity.

If we want to represent a group of objects as key-value pairs then we should go forDictionary.

Eg:
    rollno---name
    phone number--address
    ipaddress - domain name

Duplicate keys are not allowed but values can be duplicated.
Hetrogeneous objects are allowed for both key and values.
insertion order is not preserved
Dictionaries are
mutableDictionaries are
dynamic
indexing and slicing concepts are not applicable

Note: In C++ and Java Dictionaries are known as "Map" where as in Perl and Ruby it is known as "Hash"

How to create Dictionary?

d={}   or   d=dict()
we are creating empty dictionary. We can add entries as follows

d[100]="durga
"
d[200]="ravi"
d[300]="shiva
"
print(d) #{100: 'durga', 200: 'ravi', 300: 'shiva'}

If we know data in advance then we can create dictionary as follows

d={100:'durga' ,200:'ravi', 300:'shiva'}

 d={key:value, key:value}

How to access data from the dictionary?

We can access data by using keys.

d={100:'durga' ,200:'ravi',
300:'shiva'}print(d[100])
            #durga
print(d[300])   #shiva

 If the specified key is not available then we will get

 KeyErrorprint(d[400]) # KeyError: 400

 We can prevent this by checking whether key is already available or not by usinghas_key() function or by using in operator.

 d.has_key(400) ==> returns 1 if key is available otherwise returns 0

 But has_key() function is available only in Python 2 but not in Python 3. Hencecompulsory we have to use in operator.

 if 400 in d:
      print(d[400])

Q. Write a program to enter name and percentage marks in a dictionary and display information on the screen

```
1)  rec={}
2)  n=int(input("Enter number of students: "))
3)  i=1
4)  while i <=n:
5)     name=input("Enter Student Name: ")
6)     marks=input("Enter % of Marks of Student: ")
7)     rec[name]=marks
8)     i=i+1
9)  print("Name of Student","\t","% of marks")
10) for x in rec:
11)    print("\t",x,"\t\t",rec[x])
12)
13) Output
14) D:\Python_classes>py test.py
15) Enter number of students: 3
16) Enter Student Name: durga
17) Enter % of Marks of Student: 60%
18) Enter Student Name: ravi
19) Enter % of Marks of Student: 70%
20) Enter Student Name: shiva
```

21) **Enter % of Marks of Student: 80%**
22) **Name of Student   % of marks**
23) **   durga   60%**
24) **   ravi   70 %**
25) **   shiva   80%**

How to update dictionaries?

d[key]=value

 If the key is not available then a new entry will be added to the dictionary with the specified key-value pair

 If the key is already available then old value will be replaced with new value.

 Eg:

1.   d={100:**"durga"**,200:**"ravi"**,300:**"shiva"**}
2. **print**(d)
3.   d[400]=**"pavan"**
4. **print**(d)
5.   d[100]=**"sunny"**
6. **print**(d)
7.
8. **Output**
9. {100: **'durga'**, 200: **'ravi'**, 300: **'shiva'**}
10. {100: **'durga'**, 200: **'ravi'**, 300: **'shiva'**, 400: **'pavan'**}
11. {100: **'sunny'**, 200: **'ravi'**, 300: **'shiva'**, 400: **'pavan'**}

How to delete elements from dictionary?

del d[key]

 It deletes entry associated with the specified key.
 If the key is not available then we will get
 KeyError

 Eg:

1. d={100:**"durga"**,200:**"ravi"**,300:**"shiva"**}
2. **print**(d)
3. **del** d[100]
4. **print**(d)
5. **del** d[400]
6.
7. **Output**
8. {100: **'durga'**, 200: **'ravi'**, 300: **'shiva'**}

9. `{200: 'ravi', 300: 'shiva'}`
10. `KeyError: 400`

d.clear()

To remove all entries from the

dictionary**Eg:**

1. `d={100:"durga",200:"ravi",300:"shiva"}`
2. `print(d)`
3. `d.clear()`
4. `print(d)`
5.
6. `Output`
7. `{100: 'durga', 200: 'ravi', 300: 'shiva'}`
8. `{}`

del d

To delete total dictionary.Now we cannot access d

Eg:

1. `d={100:"durga",200:"ravi",300:"shiva"}`
2. `print(d)`
3. `del d`
4. `print(d)`
5.
6. `Output`
7. `{100: 'durga', 200: 'ravi', 300: 'shiva'}`
8. `NameError: name 'd' is not defined`

Important functions of dictionary:

1. dict():

To create a dictionary

d=dict() ===>It creates empty dictionary
d=dict({100:"durga",200:"ravi"}) ==>It creates dictionary with specified elements
d=dict([(100,"durga"),(200,"shiva"),(300,"ravi")])==>It creates dictionary with the givenlist of tuple elements

2. len()

Returns the number of items in the dictionary

3. clear():

To remove all elements from the dictionary

4. get():

To get the value associated with the key

d.get(key)
   If the key is available then returns the corresponding value otherwise returns None.It wont raise any error.

d.get(key,defaultvalue)
   If the key is available then returns the corresponding value otherwise returns default value.

Eg:

```
d={100:"durga",200:"ravi",300:"shiva"}
print(d[100]) ==>durga
print(d[400]) ==>KeyError:400
print(d.get(100)) ==durga
print(d.get(400)) ==>None
print(d.get(100,"Guest"))
==durga
print(d.get(400,"Guest"))
==>Guest
```

3. pop():

d.pop(key)
   It removes the entry associated with the specified key and returns the corresponding value
   If the specified key is not available then we will get KeyError

Eg:

```
1)  d={100:"durga",200:"ravi",300:"shiva"}
2)  print(d.pop(100))
3)  print(d)
4)  print(d.pop(400))
5)
6)  Output
```

7) **durga**
8) **{200: 'ravi', 300: 'shiva'}**
9) **KeyError: 400**

4. popitem():

It removes an arbitrary item(key-value) from the dictionary and

returns it.**Eg:**

1) **d={100:"durga",200:"ravi",300:"shiva"}**
2) **print(d)**
3) **print(d.popitem())**
4) **print(d)**
5)
6) **Output**
7) **{100: 'durga', 200: 'ravi', 300: 'shiva'}**
8) **(300, 'shiva')**
9) **{100: 'durga', 200: 'ravi'}**

If the dictionary is empty then we will get
KeyErrord={}
print(d.popitem()) ==>KeyError: 'popitem(): dictionary is empty'

5. keys():

It returns all keys associated eith

dictionary**Eg:**

1) **d={100:"durga",200:"ravi",300:"shiva"}**
2) **print(d.keys())**
3) **for k in d.keys():**
4) **print(k)**
5)
6) **Output**
7) **dict_keys([100, 200, 300])**
8) **100**
9) **200**
10) **300**

6. values():

It returns all values   associated with the dictionary

Eg:

```
1.  d={100:"durga",200:"ravi",300:"shiva"}
2.  print(d.values())
3.  for v in d.values():
4.      print(v)
5.
6.  Output
7.  dict_values(['durga', 'ravi', 'shiva'])
8.  durga
9.  ravi
10. shiva
```

7. items():

It returns list of tuples representing key-value

pairs.[(k,v),(k,v),(k,v)]

Eg:

```
1.  d={100:"durga",200:"ravi",300:"shiva"}
2.  for k,v in d.items():
3.      print(k,"--",v)
4.
5.  Output
6.  100 -- durga
7.  200 -- ravi
8.  300 -- shiva
```

8. copy():

To create exactly duplicate dictionary(cloned copy)

d1=d.copy();

9. setdefault():

d.setdefault(k,v)
    If the key is already available then this function returns the corresponding value.
    If the key is not available then the specified key-value will be added as new item to thedictionary.

Eg:

```
1.  d={100:"durga",200:"ravi",300:"shiva"}
2.  print(d.setdefault(400,"pavan"))
3.   print(d)
4.  print(d.setdefault(100,"sachin"))
5.   print(d)
6.
7.  Output
8.  pavan
9.  {100: 'durga', 200: 'ravi', 300: 'shiva', 400: 'pavan'}
10. durga
11. {100: 'durga', 200: 'ravi', 300: 'shiva', 400: 'pavan'}
```

10. update():

d.update(x)

   All items present in the dictionary x will be added to dictionary d

Q. Write a program to take dictionary from the keyboard and print the sumof values?

```
1.  d=eval(input("Enter dictionary:"))
2.  s=sum(d.values())
3.  print("Sum= ",s)
4.
5.  Output
6.  D:\Python_classes>py test.py
7.  Enter dictionary:{'A':100,'B':200,'C':300}
8.  Sum=  600
```

Q. Write a program to find number of occurrences of each letter present in the given string?

```
1.  word=input("Enter any word: ")
2.  d={}
3.  for x in word:
4.     d[x]=d.get(x,0)+1
5.  for k,v in d.items():
6.     print(k,"occurred ",v," times")
7.
8.  Output
9.  D:\Python_classes>py test.py
10. Enter any word: mississippi
11. m occurred  1  times
12. i occurred  4  times
13. s occurred  4  times
```

Q. Write a program to find number of occurrences of each vowel present in the given string?

```
1.  word=input("Enter any word: ")
2.  vowels={'a','e','i','o','u'}
3.  d={}
4.  for x in word:
5.      if x in vowels:
6.          d[x]=d.get(x,0)+1
7.  for k,v in sorted(d.items()):
8.      print(k,"occurred ",v," times")
9.
10. Output
11. D:\Python_classes>py test.py
12. Enter any word: doganimaldoganimal
13. a occurred  4  times
14. i occurred  2  times
15. o occurred  2  times
```

Q. Write a program to accept student name and marks from the keyboard and creates a dictionary. Also display student marks by taking student nameas input?

```
1)  n=int(input("Enter the number of students: "))
2)  d={}
3)  for i in range(n):
4)      name=input("Enter Student Name: ")
5)      marks=input("Enter Student Marks: ")
6)      d[name]=marks
7)  while True:
8)      name=input("Enter Student Name to get Marks: ")
9)      marks=d.get(name,-1)
10)     if marks== -1:
11)         print("Student Not Found")
12)     else:
13)         print("The Marks of",name,"are",marks)
14)     option=input("Do you want to find another student marks[Yes|No]")
15)     if option=="No":
16)         break
17) print("Thanks for using our application")
18)
19) Output
20) D:\Python_classes>py test.py
21) Enter the number of students: 5
22) Enter Student Name: sunny
23) Enter Student Marks: 90
```

24) **Enter Student Name: banny**
25) **Enter Student Marks: 80**
26) **Enter Student Name: chinny**
27) **Enter Student Marks: 70**
28) **Enter Student Name: pinny**
29) **Enter Student Marks: 60**
30) **Enter Student Name: vinny**
31) **Enter Student Marks: 50**
32) **Enter Student Name to get Marks: sunny**
33) **The Marks of sunny are 90**
34) **Do you want to find another student marks[Yes|No]Yes**
35) **Enter Student Name to get Marks: durga**
36) **Student Not Found**
37) **Do you want to find another student marks[Yes|No]No**
38) **Thanks for using our application**

Dictionary Comprehension:

Comprehension concept applicable for dictionaries also.

1. **squares={x:x*x for x in range(1,6)}**
2. **print(squares)**
3. **doubles={x:2*x for x in range(1,6)}**
4. **print(doubles)**
5.
6. **Output**
7. **{1: 1, 2: 4, 3: 9, 4: 16, 5: 25}**
8. **{1: 2, 2: 4, 3: 6, 4: 8, 5: 10}**

FUNCTIONS

If a group of statements is repeatedly required then it is not recommended to write these statements every time separately have to define these statements as a single unit and we can call that unit any number of times based on our requirement without rewriting.
This unit is nothing but function.

The main advantage of functions is code Reusability.
 Note: In other languages functions are known as methods, procedures, subroutines

etc

 Python supports 2 types of functions

1. Built in Functions
2. User Defined Functions

1. Built in Functions:

The functions which are coming along with Python software automatically, are called builtin functions or pre-defined functions

Eg:
id()
type()
input(
)eval()
etc..

2. User Defined Functions:

 The functions which are developed by programmer explicitly according to business requirements ,are called user defined functions.

Syntax to create user defined functions:

```
def   function_name(parameters)
  :""" doc string"""
  ----
  -----
  return value
```

Note: While creating functions we can use 2 keywords
1. def (mandatory)
2. return (optional)

Eg 1: Write a function to print Hello

test.py:

```
1)  def wish():
2)      print("Hello Good Morning")
3)  wish()
4) wish()
5)  wish()
```

Parameters

Parameters are inputs to the function. If a function contains parameters, then at the timeof calling, compulsory we should provide values otherwise, otherwise we will get error.

Eg: Write a function to take name of the student as input and print wish message by name.

```
1.  def wish(name):
2.      print("Hello",name," Good Morning")
3. wish("Durga")
4. wish("Ravi")
5.
6.
7.  D:\Python_classes>py test.py
8.  Hello Durga  Good Morning
9.   Hello Ravi  Good Morning
```

Eg: Write a function to take number as input and print its square value

```
1.  def squareIt(number):
2.      print("The Square of",number,"is", number*number)
3.  squareIt(4)
4.  squareIt(5)
5.
6.  D:\Python_classes>py test.py
7.  The Square of 4 is 16
8.  The Square of 5 is 25
```

Return Statement:

Function can take input values as parameters and executes business logic, and returnsoutput to the caller with return statement.

Q. Write a function to accept 2 numbers as input and return sum.

```
1.  def add(x,y):
2.      return x+y
3.  result=add(10,20)
4.  print("The sum is",result)
5.  print("The sum is",add(100,200))
6.
7.
8.  D:\Python_classes>py test.py
9.  The sum is 30
10. The sum is 300
```

If we are not writing return statement then default return value is None

Eg:

```
1.  def  f1():
2.      print("Hello")
3.  f1()
4.  print(f1())
5.
6.  Output
7.  Hello
8.  Hello
9.  None
```

Q. Write a function to check whether the given number is even or odd?

```
1.  def even_odd(num):
2.      if num%2==0:
3.          print(num,"is Even Number")
4.      else:
5.          print(num,"is Odd Number")
6.  even_odd(10)
7.  even_odd(15)
8.
9.  Output
10. D:\Python_classes>py test.py
11. 10 is Even Number
12. 15 is Odd Number
```

Q. Write a function to find factorial of given number?

```
1)  def fact(num):
2)      result=1
3)      while num>=1:
4)          result=result*num
5)          num=num-1
6)      return result
7)  for i in range(1,5):
8)      print("The Factorial of",i,"is :",fact(i))
9)
10) Output
11) D:\Python_classes>py test.py
12) The Factorial of 1 is : 1
13) The Factorial of 2 is : 2
14) The Factorial of 3 is : 6
15) The Factorial of 4 is : 24
```

Returning multiple values from a function:

In other languages like C,C++ and Java, function can return atmost one value. But in Python, a function can return any number of values.

Eg 1:

```
1)  def sum_sub(a,b):
2)      sum=a+b
3)      sub=a-b
4)      return sum,sub
5)  x,y=sum_sub(100,50)
6)  print("The Sum is :",x)
7)  print("The Subtraction is :",y)
8)
9)  Output
10) The Sum is : 150
11) The Subtraction is : 50
```

Eg 2:

```
1)  def calc(a,b):
2)      sum=a+b
3)      sub=a-b
4)      mul=a*b
5)      div=a/b
6)      return sum,sub,mul,div
7)  t=calc(100,50)
8)  print("The Results are")
```

```
9)  for i in t:
10)    print(i)
11)
12) Output
13) The Results are
14) 150
15) 50
16) 5000
17) 2.0
```

Types of arguments

def f1(a,b):

   ------
 f1(10,20)

 a,b are formal arguments where as 10,20 are actual arguments

There are 4 types are actual arguments are allowed in Python.

1. positional arguments
2. keyword arguments
3. default arguments
4. Variable length arguments

1. positional arguments:

These are the arguments passed to function in correct positional order.

def sub(a,b):
 print(a-b)

sub(100,200)
sub(200,100)

The number of arguments and position of arguments must be matched. If we change the order then result may be changed.

If we change the number of arguments then we will get error.

2. keyword arguments:

We can pass argument values by keyword i.e by parameter

name.**Eg:**

```
1. def wish(name,msg):
2.     print("Hello",name,msg)
3. wish(name="Durga",msg="Good Morning")
4. wish(msg="Good Morning",name="Durga")
5.
6. Output
7. Hello Durga Good Morning
8. Hello Durga Good Morning
```

Here the order of arguments is not important but number of arguments must be

matched.**Note:**

We can use both positional and keyword arguments simultaneously. But first we have totake positional arguments and then keyword arguments,otherwise we will get syntaxerror.

```
def wish(name,msg):
        print("Hello",name,msg)
wish("Durga","GoodMorning")        ==>valid
wish("Durga",msg="GoodMorning")        ==>valid
wish(name="Durga","GoodMorning") ==>invalid
SyntaxError: positional argument follows keyword
argument
```

3. Default Arguments:

 Sometimes we can provide default values for our positional arguments.

Eg:

```
1) def wish(name="Guest"):
2)     print("Hello",name,"Good Morning")
3)
4) wish("Durga")
5)  wish()
6)
7)  Output
8) Hello Durga Good Morning
9) Hello Guest Good Morning
```

If we are not passing any name then only default value will be considered.

***Note:

After default arguments we should not take non default arguments

def wish(name="Guest",msg="Good Morning"):
===>Validdef wish(name,msg="Good Morning"):
===>Valid
def wish(name="Guest",msg): ==>Invalid

SyntaxError: non-default argument follows default argument

4. Variable length arguments:

Sometimes we can pass variable number of arguments to our function,such type of arguments are called variable length arguments.

We can declare a variable length argument with * symbol as follows

def f1(*n):

We can call this function by passing any number of arguments including zero number.Internally all these values represented in the form of tuple.

Eg:

```
1)  def sum(*n):
2)      total=0
3)      for n1 in n:
4)          total=total+n1
5)      print("The Sum=",total)
6)
7)  sum()
8)  sum(10)
9)  sum(10,20)
10) sum(10,20,30,40)
11)
12) Output
13) The Sum= 0
14) The Sum= 10
15) The Sum= 30
16) The Sum= 100
```

Note:
We can mix variable length arguments with positional arguments.

Eg:

```
1)  def f1(n1,*s):
2)     print(n1)
3)     for s1 in s:
4)         print(s1)
5)
6)  f1(10)
7)  f1(10,20,30,40)
8)  f1(10,"A",30,"B")
9)
10) Output
11) 10
12) 10
13) 20
14) 30
15) 40
16) 10
17) A
18) 30
19) B
```

Note: After variable length argument, if we are taking any other arguments then we should provide values as keyword arguments.

Eg:

```
1)  def f1(*s,n1):
2)     for s1 in s:
3)         print(s1)
4)     print(n1)
5)
6)  f1("A","B",n1=10)
7)  Output
8)  A
9)  B
10) 10
```

f1("A","B",10) ==>Invalid
TypeError: f1() missing 1 required keyword-only argument: 'n1'

Note: We can declare key word variable length arguments also.
For this we have to use **.

def f1(**n):

We can call this function by passing any number of keyword arguments. Internally these keyword arguments will be stored inside a dictionary.

Eg:

```
1) def display(**kwargs):
2)    for k,v in kwargs.items():
3)        print(k,"=",v)
4) display(n1=10,n2=20,n3=30)
5) display(rno=100,name="Durga",marks=70,subject="Java")
6)
7) Output
8) n1 = 10
9) n2 = 20
10) n3 = 30
11) rno = 100
12) name = Durga
13) marks = 70
14) subject = Java
```

Case Study:

```
def f(arg1,arg2,arg3=4,arg4=8):
        print(arg1,arg2,arg3,arg4)
```

1. f(3,2) ==> 3 2 4 8

2. f(10,20,30,40) ===>10 20 30 40

3. f(25,50,arg4=100) ==>25 50 4 100

4. f(arg4=2,arg1=3,arg2=4)===>3 4 4 2
5. f()===>Invalid
   TypeError: f() missing 2 required positional arguments: 'arg1' and 'arg2'

6. f(arg3=10,arg4=20,30,40)   ==>Invalid
   SyntaxError: positional argument follows keyword argument
   [After keyword arguments we should not take positional arguments]

7. f(4,5,arg2=6)==>Invalid
   TypeError: f() got multiple values for argument 'arg2'

8. f(4,5,arg3=5,arg5=6)==>Invalid
   TypeError: f() got an unexpected keyword argument 'arg5'

Note: Function vs Module vs Library:

1. A group of lines with some name is called a function

2. A group of functions saved to a file , is called Module

3. A group of Modules is nothing but Library

Library

Function

Module 1	Module 2
Function 1	**Function 1**
Function 2	**Function 2**
Function 3	**Function 3**

```
-----------------
-----------------
-----------------
-----------------
-----------------
-----------------
-----------------
-----------------
-----------------
```

Types of Variables

Python supports 2 types of variables.

1. Global Variables
2. Local Variables

1. Global Variables

The variables which are declared outside of function are called global variables.
These variables can be accessed in all functions of that module.

Eg:

```
1)  a=10  # global variable
2)  def f1():
3)     print(a)
4)
5)  def f2():
6)     print(a)
7)
8)  f1()
9)  f2()
10)
11) Output
12) 10
13) 10
```

2. Local Variables:

The variables which are declared inside a function are called local variables.
Local variables are available only for the function in which we declared it.i.e from
outsideof function we cannot access.

Eg:

```
1) def f1():
2)     a=10
3)     print(a)  # valid
4)
5) def f2():
6)     print(a)    #invalid
7)
8) f1()
9) f2()
10)
11) NameError: name 'a' is not defined
```

global keyword:

We can use global keyword for the following 2 purposes:

1. To declare global variable inside function
2. To make global variable available to the function so that we can perform
requiredmodifications

Eg 1:

```
1)  a=10
2)  def f1():
3)      a=777
4)      print(a)
5)
6)  def f2():
7)      print(a)
8)
9)  f1()
10) f2()
11)
12) Output
13) 777
14) 10
```

Eg 2:

```
1)  a=10
2)  def f1():
3)      global a
4)      a=777
5)      print(a)
6)
7)  def f2():
8)      print(a)
9)
10) f1()
11) f2()
12)
13) Output
14) 777
15) 777
```

Eg 3:

```
1)  def f1():
2)      a=10
3)      print(a)
4)
5)  def f2():
6)      print(a)
7)
8)  f1()
9)  f2()
10)
11) NameError: name 'a' is not defined
```

Eg 4:

```
1)  def f1():
2)      global a
3)      a=10
4)      print(a)
5)
6)  def f2():
7)      print(a)
8)
9)  f1()
10) f2()
11)
12) Output
13) 10
14) 10
```

Note: If global variable and local variable having the same name then we can access global variable inside a function as follows

```
1)  a=10    #global variable
2)  def f1():
3)      a=777  #local variable
4)      print(a)
5)      print(globals()['a'])
6)  f1()
7)
8)
9)  Output
10) 777
11) 10
```

Recursive Functions

A function that calls itself is known as Recursive Function.

Eg:
factorial(3)=3*factorial(2)
          =3*2*factorial(1)
          =3*2*1*factorial(0)
          =3*2*1*1
              =6
factorial(n)= n*factorial(n-1)

The main advantages of recursive functions are:

1. **We can reduce length of the code and improves readability**
2. **We can solve complex problems very easily.**

Q. Write a Python Function to find factorial of given number with recursion.

Eg:

```
1)   def factorial(n):
2)     if n==0:
3)        result=1
4)     else:
5)        result=n*factorial(n-1)
6)     return result
7)  print("Factorial of 4 is :",factorial(4))
8)  print("Factorial of 5 is :",factorial(5))
9)
10) Output
```

Anonymous Functions:

Sometimes we can declare a function without any name, such type of nameless functions are called anonymous functions or lambda functions.

The main purpose of anonymous function is just for instant use(i.e for one time usage)

Normal Function:

We can define by using def keyword.def squareIt(n):
   return n*n

lambda Function:

We can define by using lambda keyword

lambda n:n*n

Syntax of lambda Function:

lambda argument_list : expression

<u>Note:</u> By using Lambda Functions we can write very concise code so that readability ofthe program will be improved.

Q. Write a program to create a lambda function to find square of givennumber?

```
1) s=lambda n:n*n
2) print("The Square of 4 is :",s(4))
3) print("The Square of 5 is :",s(5))
4)
5) Output
6) The Square of 4 is : 16
7) The Square of 5 is : 25
```

Q. Lambda function to find sum of 2 given numbers

```
1) s=lambda a,b:a+b
2) print("The Sum of 10,20 is:",s(10,20))
```

```
3) print("The Sum of 100,200 is:",s(100,200))
4)
5) Output
6) The Sum of 10,20 is: 30
7) The Sum of 100,200 is: 300
```

Q. Lambda Function to find biggest of given values.

```
1)   s=lambda a,b:a if a>b else b
2) print("The Biggest of 10,20 is:",s(10,20))
3) print("The Biggest of 100,200 is:",s(100,200))
4)
5) Output
6) The Biggest of 10,20 is: 20
7) The Biggest of 100,200 is: 200
```

Note:
Lambda Function internally returns expression value and we are not required to write return statement explicitly.

Note: Sometimes we can pass function as argument to another function. In such cases lambda functions are best choice.

We can use lambda functions very commonly with filter(),map() and reduce() functions,b'z these functions expect function as argument.

filter() function:

We can use filter() function to filter values from the given sequence based on some condition.

filter(function,sequence)

where function argument is responsible to perform conditional check
sequence can be list or tuple or string.

Q. Program to filter only even numbers from the list by using filter() function?

without lambda Function:

```
1) def isEven(x):
2)    if x%2==0:
3)       return True
4)    else:
```

```
5)      return False
6) l=[0,5,10,15,20,25,30]
7) l1=list(filter(isEven,l))
8) print(l1)  #[0,10,20,30]
```

with lambda Function:

```
1) l=[0,5,10,15,20,25,30]
2) l1=list(filter(lambda x:x%2==0,l))
3) print(l1)   #[0,10,20,30]
4) l2=list(filter(lambda x:x%2!=0,l))
5) print(l2) #[5,15,25]
```

map() function:

For every element present in the given sequence,apply some functionality and generatenew element with the required modification. For this requirement we should go for map() function.

Eg: For every element present in the list perform double and generate new list of doubles.

Syntax:

map(function,sequence)

The function can be applied on each element of sequence and generates new sequence.

Eg: Without lambda

```
1)   l=[1,2,3,4,5]
2) def doubleIt(x):
3)     return 2*x
4) l1=list(map(doubleIt,l))
5) print(l1) #[2, 4, 6, 8, 10]
```

with lambda

```
1) l=[1,2,3,4,5]
2) l1=list(map(lambda x:2*x,l))
3)  print(l1)  #[2, 4, 6, 8, 10]
```

Eg 2: **To find square of given numbers**

```
1.  l=[1,2,3,4,5]
2.  l1=list(map(lambda x:x*x,l))
3.  print(l1)    #[1, 4, 9, 16, 25]
```

We can apply map() function on multiple lists also.But make sure all list should have samelength.

Syntax: **map(lambda**
x,y:x*y,l1,l2))x is from l1
and y is from l2

Eg:

```
1.  l1=[1,2,3,4]
2.  l2=[2,3,4,5]
3.  l3=list(map(lambda x,y:x*y,l1,l2))
4.  print(l3)    #[2, 6, 12, 20]
```

reduce() function:

reduce() function reduces sequence of elements into a single element by applying thespecified function.

reduce(function,sequence)

reduce() function present in functools module and hence we should write import statement.

Eg:

```
1)  from functools import *
2)  l=[10,20,30,40,50]
3)  result=reduce(lambda x,y:x+y,l)
4)  print(result) # 150
```

Eg:

```
1)  result=reduce(lambda x,y:x*y,l)
2)  print(result)   #12000000
```

Eg:

```
1)  from functools import *
2)  result=reduce(lambda x,y:x+y,range(1,101))
3)  print(result)  #5050
```

Note:
- **In Python every thing is treated as object.**
- **Even functions also internally treated as objects only.**

Eg:

```
1)  def f1():
2)      print("Hello")
3)  print(f1)
4)  print(id(f1))
```

Output
<function f1 at
0x00419618>4298264

Function Aliasing:

For the existing function we can give another name, which is nothing but function aliasing.

Eg:

```
1)  def wish(name):
2)      print("Good Morning:",name)
3)
4)  greeting=wish
5)  print(id(wish))
6)  print(id(greeting))
7)
8)  greeting('Durga')
9)  wish('Durga')
```

Output
4429336
4429336
Good Morning:
DurgaGood
Morning: Durga

Note: **In the above example only one function is available but we can call that function by usingeither wish name or greeting name.**

If we delete one name still we can access that function by using alias name

Eg:

```
1)  def wish(name):
2)      print("Good Morning:",name)
```

```
3)
4) greeting=wish
5)
6) greeting('Durga')
7) wish('Durga')
8)
9) del wish
10) #wish('Durga')  ==>NameError: name 'wish' is not defined
11) greeting('Pavan')
```

Output
Good   Morning:
Durga   Good
Morning: Durga
Good   Morning:
Pavan

Nested Functions:

We can declare a function inside another function, such type of functions are called Nestedfunctions.

Eg:

```
1)  def outer():
2)      print("outer function started")
3)      def inner():
4)          print("inner function execution")
5)      print("outer function calling inner function")
6)      inner()
7)  outer()
8)  #inner()   ==>NameError: name 'inner' is not defined
```

Output
outer function started
outer function calling inner
functioninner function execution

In the above example inner() function is local to outer() function and hence it is not possible to calldirectly from outside of outer() function.

 Note: A function can return another function.

Eg:

```
1)  def outer():
2)      print("outer function started")
3)      def inner():
4)          print("inner function execution")
```

```
5)      print("outer function returning inner function")
6)      return inner
7)  f1=outer()
8)  f1()
9)  f1()
10) f1()
```

Output
outer function started
outer function returning inner
functioninner function execution
inner function
executioninner function
execution

# Q. What is the differenece between the following lines?
f1 = outer
f1 = outer()

- In the first case for the outer() function we are providing another name f1(function aliasing).
- But in the second case we calling outer() function,which returns inner function.For that innerfunction() we are providing another name f1
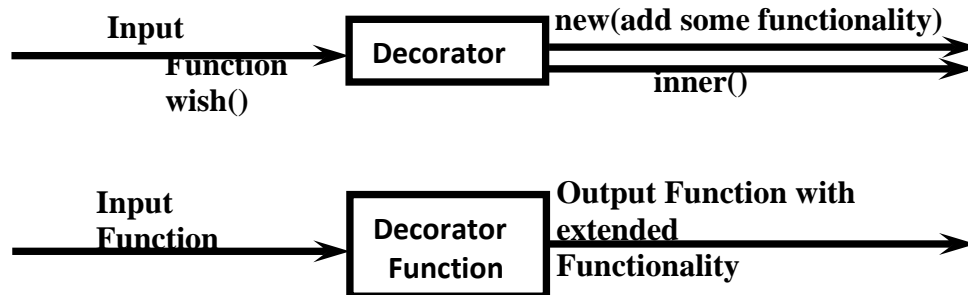

Note: We can pass function as argument to another function

Eg: filter(function,sequence)
map(function,sequence)
reduce(function,sequence)

Function Decorators:

Decorator is a function which can take a function as argument and extend its functionalityand returns modified function with extended functionality.

The main objective of decorator functions is we can extend the functionality of existing functions without modifies that function.

```
1)  def wish(name):
2)      print("Hello",name,"Good Morning")
```

This function can always print same output for any name

Hello Durga Good Morning
Hello Ravi Good Morning
Hello Sunny Good
Morning

But we want to modify this function to provide different message if name is Sunny.We can do this without touching wish() function by using decorator.

Eg:

```
1)  def decor(func):
2)      def inner(name):
3)          if name=="Sunny":
4)              print("Hello Sunny Bad Morning")
5)          else:
6)              func(name)
7)      return inner
8)
9)  @decor
10) def wish(name):
11)     print("Hello",name,"Good Morning")
12)
13) wish("Durga")
14) wish("Ravi")
15) wish("Sunny")
16)
```

17) Output
18) Hello Durga Good Morning
19) Hello Ravi Good Morning
20) Hello Sunny Bad Morning

 In the above program whenever we call wish() function automatically decor function willbe executed.

How to call same function with decorator and without decorator:

We should not use @decor

```
1)  def decor(func):
2)      def inner(name):
3)        if name=="Sunny":
4)          print("Hello Sunny Bad Morning")
5)        else:
6)          func(name)
7)      return inner
8)
9)
10) def wish(name):
11)    print("Hello",name,"Good Morning")
12)
13) decorfunction=decor(wish)
14)
15) wish("Durga") #decorator wont be executed
16) wish("Sunny") #decorator wont be executed
17)
18) decorfunction("Durga")#decorator will be executed
19) decorfunction("Sunny")#decorator will be executed
20)
21) Output
22) Hello Durga Good Morning
23) Hello Sunny Good Morning
24) Hello Durga Good Morning
25) Hello Sunny Bad Morning
```

Eg 2:

```
1)  def  smart_division(func):
2)      def inner(a,b):
3)        print("We are dividing",a,"with",b)
4)        if b==0:
5)          print("OOPS...cannot divide")
6)          return
7)        else:
8)          return func(a,b)
```

```
9)     return inner
10)
11) @smart_division
12) def  division(a,b):
13)    return a/b
14)
15) print(division(20,2))
16) print(division(20,0))
17)
18) without decorator we will get Error.In this case output is:
19)
20) 10.0
21) Traceback (most recent call last):
22)  File "test.py", line 16, in <module>
23)    print(division(20,0))
24)  File "test.py", line 13, in division
25)    return a/b
26) ZeroDivisionError: division by zero
```

with decorator we won't get any error. In this case output is:

We are dividing 20 with 2
10.0
We are dividing 20 with
0OOPS...cannot divide
None

Decorator Chaining

We can define multiple decorators for the same function and all these decorators willform Decorator Chaining.

Eg:
@decor1
@decor
def
num():

For num() function we are applying 2 decorator functions. First inner decorator will workand then outer decorator.

Eg:

```
1)  def decor1(func):
2)    def inner():
3)      x=func()
4)      return x*x
```

```
5)      return inner
6)
7)  def decor(func):
8)      def inner():
9)          x=func()
10)         return 2*x
11)     return inner
12)
13) @decor1
14) @decor
15) def num():
16)     return 10
17)
18) print(num())
```

Demo Program for decorator Chaining:

```
1)  def decor(func):
2)      def inner(name):
3)          print("First Decor(decor) Function Execution")
4)          func(name)
5)      return inner
6)
7)  def decor1(func):
8)      def inner(name):
9)          print("Second Decor(decor1) Execution")
10)         func(name)
11)     return inner
12)
13) @decor1
14) @decor
15) def wish(name):
16)     print("Hello",name,"Good Morning")
17)
18) wish("Durga")
```

D:\durgaclasses>py
decaratordemo1.pySecond
Decor(decor1) Execution
First Decor(decor) Function
ExecutionHello Durga Good
Morning

Generators

**Generator is a function which is responsible to generate a sequence of values.
We can write generator functions just like ordinary functions, but it uses yield keyword
toreturn values.**
yield

Eg 1:

```
1)  def mygen():
2)      yield 'A'
3)      yield 'B'
4)      yield 'C'
5)
6)  g=mygen()
7)  print(type(g))
8)
9)  print(next(g))
10) print(next(g))
11) print(next(g))
12) print(next(g))
13)
14) Output
15) <class 'generator'>
16) A
17) B
18) C
19) Traceback (most recent call last):
20)   File "test.py", line 12, in <module>
21)     print(next(g))
22) StopIteration
```

Eg 2:

```
1)  def countdown(num):
2)      print("Start Countdown")
3)      while(num>0):
4)          yield num
5)          num=num-1
6)
7)  values=countdown(5)
8)  for x in values:
```

```
9)    print(x)
10)
11) Output
12) Start Countdown
13) 5
14) 4
15) 3
16) 2
17) 1
```

Eg 3: To generate first n numbers:

```
1)  def firstn(num):
2)      n=1
3)      while n<=num:
4)          yield n
5)          n=n+1
6)
7)  values=firstn(5)
8)  for x in values:
9)      print(x)
10)
11) Output
12) 1
13) 2
14) 3
15) 4
16) 5
```

We can convert generator into list as follows:
values=firstn(10)
l1=list(values)
print(l1)   #[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
Eg 4: To generate Fibonacci Numbers...

The next is the sum of previous 2

numbers Eg: 0,1,1,2,3,5,8,13,21,...

```
1) def fib():
2)     a,b=0,1
3)     while True:
4)         yield a
5)         a,b=b,a+b
6) for f in fib():
7)     if f>100:
8)         break
9)     print(f)
```

```
10)
11) Output
12) 0
13) 1
14) 1
15) 2
16) 3
17) 5
18) 8
19) 13
20) 21
21) 34
22) 55
23) 89
```

Advantages of Generator Functions:

1. when compared with class level iterators, generators are very easy to use
2. Improves memory utilization and performance.
3. Generators are best suitable for reading data from large number of large files
4. Generators work great for web scraping and crawling.

Generators vs Normal Collections wrt performance:

```python
1)  import random
2)  import time
3)
4)  names = ['Sunny','Bunny','Chinny','Vinny']
5)   subjects = ['Python','Java','Blockchain']
6)
7)  def people_list(num_people):
8)     results = []
9)     for i in range(num_people):
10)       person = {
11)           'id':i,
12)           'name': random.choice(names),
13)           'subject':random.choice(subjects)
14)          }
15)       results.append(person)
16)    return results
17)
18) def people_generator(num_people):
19)    for i in range(num_people):
20)       person = {
21)           'id':i,
22)           'name': random.choice(names),
23)           'major':random.choice(subjects)
```

```
24)            }
25)        yield person
26)
27) """t1 = time.clock()
28) people = people_list(10000000)
29) t2 = time.clock()'''
30)
31) t1 = time.clock()
32) people = people_generator(10000000)
33) t2 = time.clock()
34)
35) print('Took {}'.format(t2-t1))
```

Note: In the above program observe the differnce wrt execution time by using list and generators

Generators vs Normal Collections wrt Memory Utilization:

Normal Collection:

l=[x*x for x in
range(10000000000000000)]print(l[0])

We will get MemoryError in this case because all these values are required to store in the memory.

Generators:

g=(x*x for x in range(10000000000000000))
print(next(g))

Output: 0
We won't get any MemoryError because the values won't be stored at the beginning

Modules

A group of functions, variables and classes saved to a file, which is nothing but module. Every Python file (.py) acts as a module.

Eg: durgamath.py

```
1)    x=888
2)
3) def add(a,b):
4)    print("The Sum:",a+b)
5)
6) def product(a,b):
7)    print("The Product:",a*b)
```

durgamath module contains one variable and 2 functions.

If we want to use members of module in our program then we should import that module.

import modulename

We can access members by using module name.
modulename.variable
modulename.function(

)**test.py:**

```
1)  import durgamath
2) print(durgamath.x)
3)  durgamath.add(10,20)
4) durgamath.product(10,20)
5)
6)    Output
7)    888
8) The Sum: 30
9)  The Product: 200
```

Note:

whenever we are using a module in our program, for that module compiled file will be generated and stored in the hard disk permanently.

Renaming a module at the time of import (module aliasing):

Eg:
import durgamath as m

here durgamath is original module name and m is alias name.
We can access members by using alias name m

test.py:

```
1)  import durgamath as m
2)  print(m.x)
3)  m.add(10,20)
4)  m.product(10,20)
```

from ... import:

We can import particular members of module by using from ... import .
The main advantage of this is we can access members directly without using module name.

Eg:
from durgamath import
x,addprint(x)
add(10,20)
product(10,20)==> NameError: name 'product' is not defined

We can import all members of a module as
followsfrom durgamath import *

test.py:

```
1)  from durgamath import *
2)  print(x)
3)  add(10,20)
4)  product(10,20)
```

Various possibilties of import:

import modulename
import module1,module2,module3
import module1 as m
import module1 as m1,module2 as
m2,module3from module import member
from module import
member1,member2,memebr3from module import
memeber1 as x
from module import *

member aliasing:

from durgamath import x as y,add as
sumprint(y)
sum(10,20)

Once we defined as alias name,we should use alias name only and we should not
useoriginal name

 Eg:
 from durgamath import x as y
 print(x)==>NameError: name 'x' is not defined

Reloading a Module:

By default module will be loaded only once eventhough we are importing
multiplemultiple times.

Demo Program for module reloading:

```
1) import time
2) from imp import reload
3) import module1
4) time.sleep(30)
5) reload(module1)
6) time.sleep(30)
7) reload(module1)
8) print("This is test file")
```

Note: In the above program, everytime updated version of module1 will be available
toour program

module1.py:

print("This is from module1")

test.py

```
1)  import module1
2) import module1
3)  import module1
4) import module1
5) print("This is test module")
6)
7) Output
8) This is  from module1
9) This is test module
```

In the above program test module will be loaded only once eventhough we are importing multiple times.

The problem in this approach is after loading a module if it is updated outside thenupdated version of module1 is not available to our program.

We can solve this problem by reloading module explicitly based on our requirement. We can reload by using reload() function of imp module.

import imp
imp.reload(module1
)

test.py:

```
1)  import module1
2) import module1
3)  from imp import reload
4) reload(module1)
5)  reload(module1)
6) reload(module1)
7)  print("This is test module")
```

In the above program module1 will be loaded 4 times in that 1 time by default and 3 times explicitly. In this case output is

```
1)  This is  from module1
2) This is  from module1
3)  This is  from module1
4) This is  from module1
5)  This is test module
```

The main advantage of explicit module reloading is we can ensure that updated version is always available to our program.

Finding members of module by using dir() function:

Python provides inbuilt function dir() to list out all members of current module or a specified module.

dir() ===>To list out all members of current module
dir(moduleName)==>To list out all members of specified module

Eg 1: test.py

```
1)  x=10
2)  y=20
3)  def f1():
4)      print("Hello")
5)  print(dir())   # To print all members of current module
6)
7)  Output
8)  ['__annotations__', '__builtins__', '__cached__', '__doc__', '__file__', '__loader__', '__nam
        e__', '__package__', '__spec__', 'f1', 'x', 'y']
```

Eg 2: To display members of particular module:

durgamath.py:

```
1) x=888
2)
3) def add(a,b):
4)    print("The Sum:",a+b)
5)
6) def product(a,b):
7)    print("The Product:",a*b)
```

test.py:

```
1)  import durgamath
2)  print(dir(durgamath))
3)
4)  Output
5)  ['__builtins__', '__cached__', '__doc__', '__file__', '__loader__', '__name__',
6)  '__package__', '__spec__', 'add', 'product', 'x']
```

Note: For every module at the time of execution Python interpreter will add some specialproperties automatically for internal use.

Eg:__builtins__ ,__cached__,'__doc__,__file__, __loader__, __name__,__package__, __spec__

Based on our requirement we can access these properties also in our

program.**Eg: test.py:**

```
1) print(__builtins__)
2) print(__cached__)
3) print(__doc__)
4) print(__file__)
5) print(__loader__)
6) print(__name__)
7) print(__package__)
8) print(__spec__)
9)
10) Output
11) <module 'builtins' (built-in)>
12) None
13) None
```

test.py

```
1) <_frozen_importlib_external.SourceFileLoader object at 0x00572170>
2) __main__
3) None
4) None
```

The Special variable__name__:

For every Python program , a special variable__name__will be added internally. This variable stores information regarding whether the program is executed as anindividual program or as a module.

If the program executed as an individual program then the value of this variable is __main__
If the program executed as a module from some other program then the value of this variable is the name of module where it is defined.

Hence by using this __name__variable we can identify whether the program executeddirectly or as a module.

Demo program:

module1.py:

```python
1) def f1():
2)    if __name__=='__main__':
3)        print("The code executed as a program")
4)    else:
5)        print("The code executed as a module from some other program")
6) f1()
```

test.py:

```python
1) import module1
2) module1.f1()
3)
4) D:\Python_classes>py module1.py
5) The code executed as a program
6)
7) D:\Python_classes>py test.py
8) The code executed as a module from some other program
9) The code executed as a module from some other program
```

Working with math module:

Python provides inbuilt module math.
This module defines several functions which can be used for mathematical operations.
The main important functions are

1. sqrt(x)
2. ceil(x)
3. floor(x)
4. fabs(x
)5.log(x)
6. sin(x)
7. tan(x)
....

Eg:

```python
1) from math import *
2) print(sqrt(4))
3) print(ceil(10.1))
4) print(floor(10.1))
5) print(fabs(-10.6))
6) print(fabs(10.6))
```

```
7)
8) Output
9)  2.0
10) 11
11) 10
12) 10.6
13) 10.6
```

Note:
We can find help for any module by using help()

functionEg:

**import
math
help(math)**

Working with random module:

**This module defines several functions to generate random numbers.
We can use these functions while developing games,in cryptography and to generate
random numbers on fly for authentication.**

1. random() function:

**This function always generate some float value between 0 and 1 (not
inclusive)
0<x<1**

Eg:

```
1)   from random import *
2) for i in range(10):
3)     print(random())
4)
5)   Output
6)    0.4572685609302056
7) 0.6584325233197768
8) 0.15444034016553587
9)  0.18351427005232201
10) 0.1330257265904884
11) 0.9291139798071045
12) 0.6586741197891783
13) 0.8901649834019002
14) 0.25540891083913053
15) 0.7290504335962871
```

2. randint() function:

To generate random integer beween two given numbers(inclusive)

Eg:

```
1)  from random import *
2) for i in range(10):
3)     print(randint(1,100)) # generate random int value between 1 and 100(inclusive)
4)
5)  Output
6) 51
7)  44
8) 39
9)  70
10) 49
11) 74
12) 52
13) 10
14) 40
15) 8
```

3. uniform():

It returns random float values between 2 given numbers(not inclusive)

Eg:

```
1)  from random import *
2) for i in range(10):
3)     print(uniform(1,10))
4)
5) Output
6) 9.787695398230332
7) 6.81102218793548
8) 8.068672144377329
9)  8.567976357239834
10) 6.363511674803802
11) 2.176137584071641
12) 4.822867939432386
13) 6.0801725149678445
14) 7.508457735544763
15) 1.9982221862917555
```

random() ===>in between 0 and 1 (not inclusive)
randint(x,y)   ==>in between x and y (inclusive)
uniform(x,y) ==> in between x and y (not
inclusive)

4. randrange([start],stop,[step])

 returns a random number from
   rangestart<= x < stop
   start argument is optional and default value is 0
   step argument is optional and default value is 1

randrange(10)-->generates a number from 0 to 9
randrange(1,11)-->generates a number from 1 to 10
randrange(1,11,2)-->generates a number from
1,3,5,7,9

Eg 1:

```
1)  from random import *
2)  for i in range(10):
3)      print(randrange(10))
4)
5)  Output
6)  9
7)   4
8)  0
9)  2
10) 9
11) 4
12) 8
13) 9
14) 5
15) 9
```

Eg 2:

```
1)  from random import *
2)  for i in range(10):
3)      print(randrange(1,11))
4)
5)  Output
6)  2
7)  2
8)  8
9)  10
10) 3
11) 5
12) 9
13) 1
14) 6
15) 3
```

Eg 3:

```
1)   from random import *
2)  for i in range(10):
3)      print(randrange(1,11,2))
4)
5)   Output
6)  1
7)  3
8)  9
9)  5
10) 7
11) 1
12) 1
13) 1
14) 7
15) 3
```

5. choice() function:

It wont return random number.
It will return a random object from the given list or tuple.

Eg:

```
1) from random import *
2) list=["Sunny","Bunny","Chinny","Vinny","pinny"]
3) for i in range(10):
4)     print(choice(list))
```

Output
Bunny
pinny
Bunny
Sunny
Bunny
pinny
pinny
Vinny
Bunny
Sunny

Packages

It is an encapsulation mechanism to group related modules into a single unit.
package is nothing but folder or directory which represents collection of Python modules.

Any folder or directory contains __init_.py file,is considered as a Python package.This
filecan be empty.

A package can contains sub packages also.

__init__.py

File 1

File 1   **File 1**

__init__.py   **__init__.py**

x.py   **y.py**   **m.py**   **n.py**

Home Loan   **Vehicle Loan**

Loan

The main advantages of package statement are

1. **We can resolve naming conflicts**
2. **We can identify our components uniquely**
3. **It improves modularity of the**

application<u>Eg 1:</u>

D:\Python_classes>
   |-test.py
   |-pack1
      |-module1.py
      |-__init__.py

__init__.py:

empty file

<u>**module1.py:**</u>
def f1():
     print("Hello this is from module1 present in pack1")

<u>**test.py (version-1):**</u>
import
pack1.module1
pack1.module1.f1()

test.py (version-2):

from pack1.module1 import
f1f1()

Eg 2:

D:\Python_classes>
    |-test.py
    |-com
        |-module1.py

def f1():
   **print("Hello this is from module1 present in com")**

module2.py:

def f2():
      print("Hello this is from module2 present in com.durgasoft")

test.py:

```
1.  from com.module1 import f1
2.  from com.durgasoft.module2 import f2
3.  f1()
4.  f2()
5.
6.  Output
7.  D:\Python_classes>py test.py
8.  Hello this is from module1 present in com
9.  Hello this is from module2 present in com.durgasoft
```

Note: Summary diagram of library,packages,modules which contains functions,classesand variables.

Library

pack 1   pack 2   ---------------   pack n

module 1 module 2 module n   module 1 module 2 module n

function 1 function 2 function n variables classes

File Handling

As the part of programming requirement, we have to store our data permanently forfuture purpose. For this requirement we should go for files.

Files are very common permanent storage areas to store our data.

Types of Files:

There are 2 types of files

1. Text Files:

Usually we can use text files to store character
dataeg: abc.txt

2. Binary Files:

Usually we can use binary files to store binary data like images,video files, audio files etc...

Opening a File:

Before performing any operation (like read or write) on the file,first we have to open that file.For this we should use Python's inbuilt function open()

But at the time of open, we have to specify mode,which represents the purpose ofopening file.

f = open(filename, mode)

The allowed modes in Python are

1. r □ open an existing file for read operation. The file pointer is positioned at thebeginning of the file.If the specified file does not exist then we will get FileNotFoundError.This is default mode.

2. w □ open an existing file for write operation. If the file already contains some data then it will be overridden. If the specified file is not already avaialble then this mode willcreate that file.

3. a □ open an existing file for append operation. It won't override existing data.If thespecified file is not already avaialble then this mode will create a new file.

4. r+ □ To read and write data into the file. The previous data in the file will not bedeleted.The file pointer is placed at the beginning of the file.

5. w+ □ To write and read data. It will override existing data.

6. a+ □ To append and read data from the file.It wont override existing data.

7. x □ To open a file in exclusive creation mode for write operation. If the file alreadyexists then we will get FileExistsError.

<u>Note:</u> All the above modes are applicable for text files. If the above modes suffixed with'b' then these represents for binary files.

<u>Eg:</u> rb,wb,ab,r+b,w+b,a+b,xb

f = open("abc.txt","w")

We are opening abc.txt file for writing data.

Closing a File:

After completing our operations on the file,it is highly recommended to close the file. For this we have to use close() function.

f.close()

Various properties of File Object:

Once we opend a file and we got file object,we can get various details related to that file by using its properties.

name □ Name of opened file
mode □ Mode in which the file is opened
closed □ Returns boolean value indicates that file is closed or not
readable()□ Retruns boolean value indicates that whether file is readable or not
writable()□ Returns boolean value indicates that whether file is writable or not.

Eg:

```
1)  f=open("abc.txt",'w')
2)  print("File Name: ",f.name)
3)  print("File Mode: ",f.mode)
4)  print("Is File Readable:  ",f.readable())
5)  print("Is File Writable:  ",f.writable())
6)  print("Is File Closed : ",f.closed)
7)  f.close()
8)  print("Is File Closed : ",f.closed)
9)
10)
11) Output
12) D:\Python_classes>py test.py
13) File Name:  abc.txt
14) File Mode:  w
15) Is File Readable:  False
16) Is File Writable:  True
17) Is File Closed :  False
18) Is File Closed :  True
```

Writing data to text files:

We can write character data to the text files by using the following 2 methods.

write(str)
writelines(list of
lines)

Eg:

```
1)  f=open("abcd.txt",'w')
2)  f.write("Durga\n")
3)  f.write("Software\n")
4)  f.write("Solutions\n")
5)  print("Data written to the file successfully")
6)   f.close()
```

abcd.txt:
Durga
Software
Solution
s

Note: In the above program, data present in the file will be overridden everytime if we run the program. Instead of overriding if we want append operation then we should openthe file as follows.

f = open("abcd.txt","a")

Eg 2:

```
1)  f=open("abcd.txt",'w')
2) list=["sunny\n","bunny\n","vinny\n","chinny"]
3)  f.writelines(list)
4) print("List of lines written to the file successfully")
5)  f.close()
```

abcd.txt:
sunny
bunny
vinny
chinn
y

Note: while writing data by using write() methods, compulsory we have to provide lineseperator(\n),otherwise total data should be written to a single line.

Reading Character Data from text files:

We can read character data from text file by using the following read methods.

read()☐ To read total data from the file
read(n) ☐ To read 'n' characters from the
filereadline()☐ To read only one line
readlines()☐ To read all lines into a list

Eg 1: To read total data from the file

```
1)  f=open("abc.txt",'r')
2)  data=f.read()
3)  print(data)
4)  f.close()
5)
6)  Output
7)  sunny
8)  bunny
9)  chinny
10) vinny
```

Eg 2: To read only first 10 characters:

```
1)  f=open("abc.txt",'r')
2) data=f.read(10)
3)  print(data)
4) f.close()
5)
```

6) Output
7) sunny
8) bunn

Eg 3: To read data line by line:

```
1) f=open("abc.txt",'r')
2) line1=f.readline()
3) print(line1,end='')
4) line2=f.readline()
5) print(line2,end='')
6) line3=f.readline()
7) print(line3,end='')
8) f.close()
9)
10) Output
11) sunny
12) bunny
13) chinny
```

Eg 4: To read all lines into list:

```
1) f=open("abc.txt",'r')
2) lines=f.readlines()
3) for line in lines:
4)     print(line,end='')
5) f.close()
6)
7) Output
8) sunny
9) bunny
10) chinny
11) vinny
```

Eg 5:

```
1) f=open("abc.txt","r")
2) print(f.read(3))
3) print(f.readline())
4) print(f.read(4))
5) print("Remaining data")
6) print(f.read())
7)
8) Output
9) sun
10) ny
11)
12) bunn
13) Remaining data
```

The with statement:

The with statement can be used while opening a file.We can use this to group file operation statements within a block.
The advantage of with statement is it will take care closing of file,after completing all operations automatically even in the case of exceptions also, and we are not required to close explicitly.
Eg:

```
1) with open("abc.txt","w") as f:
2)     f.write("Durga\n")
3)     f.write("Software\n")
4)     f.write("Solutions\n")
5)     print("Is File Closed: ",f.closed)
6) print("Is File Closed: ",f.closed)
7)
8) Output
9) Is File Closed:  False
10) Is File Closed:  True
```

The seek() and tell() methods:

tell():

 ==>We can use tell() method to return current position of the cursor(file pointer) frombeginning of the file. [can you plese telll current cursor position]
 The position(index) of first character in files is zero just like string

index.**Eg:**

```
1) f=open("abc.txt","r")
2) print(f.tell())
3) print(f.read(2))
4) print(f.tell())
5) print(f.read(3))
6) print(f.tell())
```

abc.txt
:sunny
bunny
chinny
vinny

Output:
0
su
2
nny
5

seek():

We can use seek() method to move cursor(file pointer) to specified location.
[Can you please seek the cursor to a particular location]

f.seek(offset, fromwhere)

offset represents the number of positions

The allowed values for second attribute(from where)
are0   >From beginning of file(default value)
1>From current position
2>From end of the file

<u>Note:</u> Python 2 supports all 3 values but Python 3 supports only

zero.<u>Eg:</u>

```
1)   data="All Students are STUPIDS"
2)   f=open("abc.txt","w")
3)   f.write(data)
4)   with open("abc.txt","r+") as f:
5)     text=f.read()
6)     print(text)
7)     print("The Current Cursor Position: ",f.tell())
8)     f.seek(17)
9)     print("The Current Cursor Position: ",f.tell())
10)    f.write("GEMS!!!")
11)    f.seek(0)
12)    text=f.read()
13)    print("Data After Modification:")
14)    print(text)
15)
16) Output
17)
18) All Students are STUPIDS
19) The Current Cursor Position:  24
20) The Current Cursor Position:  17
21) Data After Modification:
```

```
22) All Students are GEMS!!!
```

How to check a particular file exists or not?

**We can use os library to get information about files in our computer.
os module has path sub module,which contains isFile() function to check whether
aparticular file exists or not?
os.path.isfile(fname)**

Q. Write a program to check whether the given file exists or not. If it isavailable then print its content?

```
1)  import os,sys
2)  fname=input("Enter File Name: ")
3)  if os.path.isfile(fname):
4)      print("File exists:",fname)
5)      f=open(fname,"r")
6)  else:
7)      print("File does not exist:",fname)
8)      sys.exit(0)
9)  print("The content of file is:")
10) data=f.read()
11) print(data)
12)
13) Output
14) D:\Python_classes>py test.py
15) Enter File Name: durga.txt
16) File does not exist: durga.txt
17)
18) D:\Python_classes>py test.py
19) Enter File Name: abc.txt
20) File exists: abc.txt
21) The content of file is:
22) All Students are GEMS!!!
23) All Students are GEMS!!!
24) All Students are GEMS!!!
25) All Students are GEMS!!!
26) All Students are GEMS!!!
27) All Students are GEMS!!!
```

Note:
**sys.exit(0) ===>To exit system without executing rest of the program.
argument represents status code . 0 means normal termination and it is the default value.**

Q. Program to print the number of lines,words and characters present in thegiven file?

```
1)  import os,sys
2)  fname=input("Enter File Name: ")
3)  if os.path.isfile(fname):
4)      print("File exists:",fname)
5)      f=open(fname,"r")
6)  else:
7)      print("File does not exist:",fname)
8)      sys.exit(0)
9)  lcount=wcount=ccount=0
10) for line in f:
11)     lcount=lcount+1
12)     ccount=ccount+len(line)
13)     words=line.split()
14)     wcount=wcount+len(words)
15) print("The number of Lines:",lcount)
16) print("The number of Words:",wcount)
17) print("The number of Characters:",ccount)18)
19) Output
20) D:\Python_classes>py test.py
21) Enter File Name: durga.txt
22) File does not exist: durga.txt23)
24) D:\Python_classes>py test.py
25) Enter File Name: abc.txt
26) File exists: abc.txt
27) The number of Lines: 6
28) The number of Words: 24
29)  The number of Characters: 149
```

abc.txt:

**All   Students   are
GEMS!!! All Students
are   GEMS!!!   All
Students are GEMS!!!
All   Students   are
GEMS!!! All Students
are   GEMS!!!   All
Students are GEMS!!!**

Handling Binary Data:

It is very common requirement to read or write binary data like images,video files,audio files etc.

Q. Program to read image file and write to a new image file?

```
1)  f1=open("rossum.jpg","rb")
2)  f2=open("newpic.jpg","wb")
3)  bytes=f1.read()
4)  f2.write(bytes)
5)  print("New Image is available with the name: newpic.jpg")
```

Handling csv files:

 CSV==>Comma seperated values

 As the part of programming,it is very common requirement to write and read data wrt csv files. Python provides csv module to handle csv files.

Writing data to csv file:

```
1)  import csv
2)  with open("emp.csv","w",newline='') as f:
3)      w=csv.writer(f)  # returns csv writer object
4)      w.writerow(["ENO","ENAME","ESAL","EADDR"])
5)      n=int(input("Enter Number of Employees:"))
6)      for i in range(n):
7)        eno=input("Enter Employee No:")
8)        ename=input("Enter Employee Name:")
9)        esal=input("Enter Employee Salary:")
10)       eaddr=input("Enter Employee Address:")
11)       w.writerow([eno,ename,esal,eaddr])
12) print("Total Employees data written to csv file successfully")
```

Note: Observe the difference with newline attribute and

withoutwith open("emp.csv","w",newline='') as f:
with open("emp.csv","w") as f:

Note: If we are not using newline attribute then in the csv file blank lines will be includedbetween data. To prevent these blank lines, newline attribute is required in Python-3,but in Python-2 just we can specify mode as 'wb' and we are not required to use newline attribute.

Reading Data from csv file:

```
1)  import csv
2)  f=open("emp.csv",'r')
3)  r=csv.reader(f) #returns csv reader object
4)  data=list(r)
5)  #print(data)
6)  for line in data:
7)      for word in line:
8)          print(word,"\t",end='')
9)      print()
10)
11) Output
12) D:\Python_classes>py test.py
13) ENO   ENAME   ESAL   EADDR
14) 100   Durga   1000   Hyd
15) 200   Sachin  2000   Mumbai
16) 300   Dhoni   3000   Ranchi
```

Zipping and Unzipping Files:

It is very common requirement to zip and unzip files.
The main advantages are:

1. To improve memory utilization
2. We can reduce transport time
3. We can improve performance.

To perform zip and unzip operations, Python contains one in-bulit module zip file.This module contains a class : ZipFile

To create Zip file:

We have to create ZipFile class object with name of the zip file,mode and constant ZIP_DEFLATED. This constant represents we are creating zip file.

f = ZipFile("files.zip","w","ZIP_DEFLATED")

Once we create ZipFile object,we can add files by using write() method.

f.write(filename)

Eg:

```
1) from zipfile import *
2) f=ZipFile("files.zip",'w',ZIP_DEFLATED)
3)   f.write("file1.txt")
4) f.write("file2.txt")
5)   f.write("file3.txt")
6) f.close()
7)   print("files.zip file created successfully")
```

To perform unzip operation:

We have to create ZipFile object as follows

f = ZipFile("files.zip","r",ZIP_STORED)

ZIP_STORED represents unzip operation. This is default value and hence we are not required to specify.
Once we created ZipFile object for unzip operation,we can get all file names present inthat zip file by using namelist() method.

names = f.namelist()

Eg:

```
1)   from zipfile import *
2)   f=ZipFile("files.zip",'r',ZIP_STORED)
3)   names=f.namelist()
4)   for name in names:
5)     print(  "File Name: ",name)
6)     print("The Content of this  file is:")
7)     f1=open(name,'r')
8)     print(f1.read())
9)     print()
```

Working with Directories:

It is very common requirement to perform operations for directories like

1. To know current working directory
2. To create a new directory
3. To remove an existing directory
4. To rename a directory
5. To list contents of the
directoryetc...

To perform these operations,Python provides inbuilt module os,which contains several functions to perform directory related operations.

Q1. To Know Current Working Directory:

```
import os
cwd=os.getcwd()
print("Current Working Directory:",cwd)
```

Q2. To create a sub directory in the current working directory:

```
import os
os.mkdir("mysub
")
print("mysub directory created in cwd")
```

Q3. To create a sub directory in mysub directory:

```
   cwd
    |-mysub
        |-mysub2
```

```
import os
os.mkdir("mysub/mysub2
")
print("mysub2  created inside mysub")
```

Note: Assume mysub already present in cwd.

Q4. To create multiple directories like sub1 in that sub2 in that sub3:

```
 import os
os.makedirs("sub1/sub2/sub3"
)
print("sub1 and in that sub2 and in that sub3 directories created")
```

Q5. To remove a directory:

```
import os
os.rmdir("mysub/mysub2")
print("mysub2 directory
deleted")
```

Q6. To remove multiple directories in the path:

```
import os
os.removedirs("sub1/sub2/sub3")
print("All 3 directories sub1,sub2 and sub3 removed")
```

Q7. To rename a directory:

import os
os.rename("mysub","newdir")
print("mysub directory renamed to newdir")

Q8. To know contents of directory:

os module provides listdir() to list out the contents of the specified directory. It won't display the contents of sub directory.

Eg:

```
1)  import os
2)  print(os.listdir("."))
3)
4)  Output
5)  D:\Python_classes>py test.py
6)  ['abc.py', 'abc.txt', 'abcd.txt', 'com', 'demo.py', 'durgamath.py', 'emp.csv', '
7)  file1.txt', 'file2.txt', 'file3.txt', 'files.zip', 'log.txt', 'module1.py', 'myl
8)  og.txt', 'newdir', 'newpic.jpg', 'pack1', 'rossum.jpg', 'test.py', '__pycache__'
9)  ]
```

The above program display contents of current working directory but not contents of subdirectories.

If we want the contents of a directory including sub directories then we should go for walk() function.

Q9. To know contents of directory including sub directories:

We have to use walk() function
[Can you please walk in the directory so that we can aware all contents of that directory]

os.walk(path,topdown=True,onerror=None,followlinks=False)

It returns an Iterator object whose contents can be displayed by using for loop

path-->Directory path. cwd means .
topdown=True --->Travel from top to
bottom
onerror=None --->on error detected which function has to execute.
followlinks=True -->To visit directories pointed by symbolic links

Eg: To display all contents of Current working directory including sub directories:

```
1) import os
2) for dirpath,dirnames,filenames in os.walk('.'):
3)     print("Current Directory Path:",dirpath)
4)     print("Directories:",dirnames)
5)     print("Files:",filenames)
6)     print()
7)
8)
9)  Output
10) Current Directory Path: .
11) Directories: ['com', 'newdir', 'pack1', '__pycache__']
12) Files: ['abc.txt', 'abcd.txt', 'demo.py', 'durgamath.py', 'emp.csv', 'file1.txt'
13) , 'file2.txt', 'file3.txt', 'files.zip', 'log.txt', 'module1.py', 'mylog.txt', '
14) newpic.jpg', 'rossum.jpg', 'test.py']
15)
16) Current Directory Path: .\com
17) Directories: ['durgasoft', '__pycache__']
18) Files: ['module1.py', '__init__.py']
19)
20) ...
```

Note: To display contents of particular directory,we have to provide that directory nameas argument to walk() function.

os.walk("directoryname")

Q. What is the difference between listdir() and walk() functions?

In the case of listdir(), we will get contents of specified directory but not sub directory contents. But in the case of walk() function we will get contents of specified directory and its sub directories also.

Running Other programs from Python program:

os module contains system() function to run programs and commands.It is exactly same as system() function in C language.

os.system("commad string")
   The argument is any command which is executing from DOS.

Eg:
import os
os.system("dir *.py")
os.system("py
abc.py")

How to get information about a File:

We can get statistics of a file like size, last accessed time,last modified time etc by usingstat() function of os module.

`stats = os.stat("abc.txt")`

The statistics of a file includes the following parameters:

st_mode==>Protection Bits
st_ino==>Inode number
st_dev===>device
st_nlink===>no of hard
links st_uid===>userid of
owner st_gid==>group id of
owner st_size===>size of file
in bytes
st_atime==>Time of most recent access
st_mtime==>Time of Most recent modification
st_ctime==> Time of Most recent meta data
change

Note:

st_atime, st_mtime and st_ctime returns the time as number of milli seconds since Jan 1st1970 ,12:00AM. By using datetime module fromtimestamp() function,we can get exact date and time.

Q. To print all statistics of file abc.txt:

```
1) import os
2) stats=os.stat("abc.txt")
3) print(stats)
4)
5) Output
6) os.stat_result(st_mode=33206, st_ino=844424930132788, st_dev=2657980798, st_nlin
7) k=1, st_uid=0, st_gid=0, st_size=22410, st_atime=1505451446, st_mtime=1505538999
8)  , st_ctime=1505451446)
```

Q. To print specified properties:

```
1) import os
2) from  datetime  import *
3) stats=os.stat("abc.txt")
4) print("File Size in Bytes:",stats.st_size)
5) print("File Last Accessed Time:",datetime.fromtimestamp(stats.st_atime))
6) print("File Last Modified Time:",datetime.fromtimestamp(stats.st_mtime))
7)
```

8) **Output**
9) **File Size in Bytes: 22410**
10) **File Last Accessed Time: 2017-09-15 10:27:26.599490**
11) **File Last Modified Time: 2017-09-16 10:46:39.245394**

Pickling and Unpickling of Objects:

Sometimes we have to write total state of object to the file and we have to read total object from the file.

The process of writing state of object to the file is called pickling and the process ofreading state of an object from the file is called unpickling.
We can implement pickling and unpickling by using pickle module of

Python.pickle module contains dump() function to perform pickling.

`pickle.dump(object,file)`

pickle module contains load() function to perform unpickling

`obj=pickle.load(file)`

Writing and Reading State of object by using pickle Module:

```
1) import pickle
2) class Employee:
3)     def __init__(self,eno,ename,esal,eaddr):
4)         self.eno=eno;
5)         self.ename=ename;
6)         self.esal=esal;
7)         self.eaddr=eaddr;
8)     def display(self):
9)         print(self.eno,"\t",self.ename,"\t",self.esal,"\t",self.eaddr)
10) with open("emp.dat","wb") as f:
11)     e=Employee(100,"Durga",1000,"Hyd")
12)     pickle.dump(e,f)
13)     print("Pickling of Employee Object completed...")
14)
15) with open("emp.dat","rb") as f:
16)     obj=pickle.load(f)
17)     print("Printing Employee Information after unpickling")
18)     obj.display()
```

Writing Multiple Employee Objects to the file:

emp.py:

```
1) class Employee:
2)     def __init__(self,eno,ename,esal,eaddr):
3)         self.eno=eno;
4)         self.ename=ename;
5)         self.esal=esal;
6)         self.eaddr=eaddr;
7)     def display(self):
8)
9)         print(self.eno,"\t",self.ename,"\t",self.esal,"\t",self.eaddr)
```

pick.py:

```
1) import emp,pickle
2) f=open("emp.dat","wb")
3) n=int(input("Enter The number of Employees:"))
4) for i in range(n):
5)     eno=int(input("Enter Employee Number:"))
6)     ename=input("Enter Employee Name:")
7)     esal=float(input("Enter Employee Salary:"))
8)     eaddr=input("Enter Employee Address:")
9)     e=emp.Employee(eno,ename,esal,eaddr)
10)    pickle.dump(e,f)
11) print("Employee Objects pickled successfully")
```

unpick.py:

```python
import emp,pickle
f=open("emp.dat","rb")
print("Employee Details:")
while True:
    try:
        obj=pickle.load(f)
        obj.display()
    except EOFError:
        print("All employees Completed")
        break
f.close()
```

Exception Handling

In any programming language there are 2 types of errors are possible.

   1. Syntax Errors
   2. Runtime Errors

1. Syntax Errors:

The errors which occurs because of invalid syntax are called syntax

errors.Eg 1:

```
x=10
if x==10
  print("Hello
  ")
```

SyntaxError: invalid

syntaxEg 2:
```
print "Hello"
```

SyntaxError: Missing parentheses in call to 'print'

Note:
Programmer is responsible to correct these syntax errors. Once all syntax errors are corrected then only program execution will be started.

2. Runtime Errors:

Also known as exceptions.
While executing the program if something goes wrong because of end user input orprogramming logic or memory problems etc then we will get Runtime Errors.

Eg: print(10/0) ==>ZeroDivisionError: division by zero

   print(10/"ten") ==>TypeError: unsupported operand type(s) for /: 'int' and 'str'

   x=int(input("Enter Number:"))
   print(x)

   D:\Python_classes>py

   test.py

Enter Number:ten
   ValueError: invalid literal for int() with base 10: 'ten'

<u>Note:</u> Exception Handling concept applicable for Runtime Errors but not for syntax errors

What is Exception:

An unwanted and unexpected event that disturbs normal flow of program is calledexception.

<u>Eg:</u>

ZeroDivisionError
TypeError
ValueError
FileNotFoundErro
r EOFError
SleepingError
TyrePuncturedErr
or

It is highly recommended to handle exceptions. The main objective of exception handlingis Graceful Termination of the program(i.e we should not block our resources and we should not miss anything)

Exception handling does not mean repairing exception. We have to define alternative wayto continue rest of the program normally.

<u>Eg:</u>

For example our programming requirement is reading data from remote file locating at London. At runtime if london file is not available then the program should not be terminated abnormally. We have to provide local file to continue rest of the program normally. This way of defining alternative is nothing but exception handling.

try:

   read data from remote file locating at london
except FileNotFoundError:
   use local file and continue rest of the program normally

Q. What is an Exception?
Q. What is the purpose of Exception Handling?
Q. What is the meaning of Exception Handling?

Default Exception Handing in Python:

Every exception in Python is an object. For every exception type the corresponding classesare available.

Whevever an exception occurs PVM will create the corresponding exception object andwill check for handling code. If handling code is not available then Python interpreter terminates the program abnormally and prints corresponding exception information tothe console.
The rest of the program won't be

executed.**Eg:**

```
1)  print("Hello")
2)  print(10/0)
3)  print("Hi")
4)
5)  D:\Python_classes>py test.py
6)  Hello
7)  Traceback (most recent call last):
8)    File "test.py", line 2, in <module>
9)      print(10/0)
10) ZeroDivisionError: division by zero
```

Python's Exception Hierarchy

```
                          BaseException
                               ▲
        ┌──────────────┬───────┴───────┬──────────────────┐
    Exception      SystemExit    GeneratorExit     KeyboardInterrupt
        ▲
 ┌──────┬────────┬──────┬──────┬──────┬──────┬──────┐
Attribut Arithmetic EOF  Name  Lookup OS    Type   Value
e       Error     Error Error Error  Error  Error  Error
Error
        ├── ZeroDivision              Index        FileNotFound
        │   Error                     Error        Error
        │                             Key          Interrupted
        ├── FloatingPoint             Error        Error
        │   Error
        │                                          Permission
        └── Overflow                               Error
            Error
                                                   TimeOut
                                                   Error
```

Every Exception in Python is a class.
All exception classes are child classes of BaseException.i.e every exception class extends BaseException either directly or indirectly. Hence BaseException acts as root for Python Exception Hierarchy.

Most of the times being a programmer we have to concentrate Exception and its child classes.

Customized Exception Handling by using try-except:

It is highly recommended to handle exceptions.
The code which may raise exception is called risky code and we have to take risky code inside try block. The corresponding handling code we have to take inside except block.

try:
  Risky
Codeexcept
XXX:
  Handling code/Alternative Code

without try-except:

```
1.   print("stmt-1")
2.  print(10/0)
3.   print("stmt-3")
4.
5.  Output
6.  stmt-1
7.  ZeroDivisionError: division by zero
```

Abnormal termination/Non-Graceful Termination

with try-except:

```
1.   print("stmt-1")
2.  try:
3.      print(10/0)
4.  except ZeroDivisionError:
5.      print(10/2)
6.  print("stmt-3")
7.
8.  Output
9.   stmt-1
10. 5.0
11. stmt-3
```

Normal termination/Graceful Termination

Control Flow in try-except:

```
try:
        stmt-1
        stmt-2
        stmt-3
except XXX:
        stmt-4
stmt-5
```

case-1: **If there is no exception**
    1,2,3,5 and Normal
    Termination

case-2: If an exception raised at stmt-2 and corresponding except block matched
    1,4,5 Normal Termination

case-3: If an exception raised at stmt-2 and corresponding except block not
    matched1, Abnormal Termination

case-4: If an exception raised at stmt-4 or at stmt-5 then it is always abnormal
termination.

Conclusions:

1. within the try block if anywhere exception raised then rest of the try block wont be executed eventhough we handled that exception. Hence we have to take only risky codeinside try block and length of the try block should be as less as possible.

2. In addition to try block,there may be a chance of raising exceptions inside except andfinally blocks also.

3. If any statement which is not part of try block raises an exception then it is alwaysabnormal termination.

How to print exception information:

try:

```
1.  print(10/0)
2.  except ZeroDivisionError as msg:
3.      print("exception raised and its description is:",msg)
4.
5.  Output exception raised and its description is: division by zero
```

try with multiple except blocks:

The way of handling exception is varied from exception to exception.Hence for every exception type a seperate except block we have to provide. i.e try with multiple except blocks is possible and recommended to use.

Eg:
try:

    ----
except
    ZeroDivisionError:
    perform alternative
    arithmetic operations

except FileNotFoundError:
    use local file instead of remote file

If try with multiple except blocks available then based on raised exception the corresponding except block will be executed.

Eg:

```
1)  try:
2)      x=int(input("Enter First Number: "))
3)      y=int(input("Enter Second Number: "))
4)      print(x/y)
5)  except ZeroDivisionError :
6)      print("Can't Divide with Zero")
7)  except ValueError:
8)      print("please provide int value only")
9)
10) D:\Python_classes>py test.py
11) Enter First Number: 10
12) Enter Second Number: 2
13) 5.0
14)
15) D:\Python_classes>py test.py
16) Enter First Number: 10
17) Enter Second Number: 0
18) Can't Divide with Zero
19)
20) D:\Python_classes>py test.py
21) Enter First Number: 10
22) Enter Second Number: ten
23) please provide int value only
```

If try with multiple except blocks available then the order of these except blocks is important .Python interpreter will always consider from top to bottom until matched except block identified.

Eg:

```
1)  try:
2)      x=int(input("Enter First Number: "))
3)      y=int(input("Enter Second Number: "))
4)      print(x/y)
5)  except ArithmeticError :
6)      print("ArithmeticError")
7)  except ZeroDivisionError:
8)      print("ZeroDivisionError")
9)
10) D:\Python_classes>py test.py
```

Single except block that can handle multiple exceptions:

We can write a single except block that can handle multiple different types of exceptions.

except (Exception1,Exception2,exception3,..): or
except (Exception1,Exception2,exception3,..) as msg
:

Parenthesis are mandatory and this group of exceptions internally considered as

tuple.**Eg:**

```
1) try:
2)     x=int(input("Enter First Number: "))
3)     y=int(input("Enter Second Number: "))
4)     print(x/y)
5) except (ZeroDivisionError,ValueError) as msg:
6)     print("Plz Provide valid numbers only and problem is: ",msg)
7)
8) D:\Python_classes>py test.py
9)  Enter First Number: 10
10) Enter Second Number: 0
11) Plz Provide valid numbers only and problem is:  division by zero
12)
13) D:\Python_classes>py test.py
14) Enter First Number: 10
15) Enter Second Number: ten
16) Plz Provide valid numbers only and problem is:  invalid literal for int() with b
17) ase 10: 'ten'
```

Default except block:

We can use default except block to handle any type of exceptions.
In default except block generally we can print normal error messages.

Syntax:
  except:
      statements
Eg:

```
1) try:
2)     x=int(input("Enter First Number: "))
3)     y=int(input("Enter Second Number: "))
4)     print(x/y)
```

```
5)  except ZeroDivisionError:
6)      print("ZeroDivisionError:Can't divide with zero")
7)  except:
8)      print("Default Except:Plz provide valid input only")
9)
10) D:\Python_classes>py test.py
11) Enter First Number: 10
12) Enter Second Number: 0
13) ZeroDivisionError:Can't divide with zero
14)
15) D:\Python_classes>py test.py
16) Enter First Number: 10
17) Enter Second Number: ten
18) Default Except:Plz provide valid input only
```

***<u>Note:</u> If try with multiple except blocks available then default except block should be last,otherwise we will get SyntaxError.

<u>Eg:</u>

```
1)  try:
2)      print(10/0)
3)  except:
4)      print("Default Except")
5)  except ZeroDivisionError:
6)      print("ZeroDivisionError")
7)
8)  SyntaxError: default 'except:' must be last
```

<u>Note:</u>

The following are various possible combinations of except blocks
1. except ZeroDivisionError:
1. except ZeroDivisionError as msg:
3. except (ZeroDivisionError,ValueError) :
4. except (ZeroDivisionError,ValueError) as msg:
5. except :

<u>finally block:</u>

1. It is not recommended to maintain clean up code(Resource Deallocating Code or Resource Releasing code) inside try block because there is no guarentee for the executionof every statement inside try block always.

2. t is not recommended to maintain clean up code inside except block, because if thereis no exception then except block won't be executed.

Hence we required some place to maintain clean up code which should be executed always irrespective of whether exception raised or not raised and whether exception handled or not handled. Such type of best place is nothing but finally block.

Hence the main purpose of finally block is to maintain clean up code.

```
try:
    Risky Code
except:
    Handling
Codefinally:
    Cleanup code
```

The speciality of finally block is it will be executed always whether exception raised or not raised and whether exception handled or not handled.

Case-1: If there is no exception

```
1)  try:
2)      print("try")
3)  except:
4)      print("except")
5)  finally:
6)      print("finally")
7)
8)  Output
9)  try
10) finally
```

Case-2: If there is an exception raised but handled:

```
1)  try:
2)      print("try")
3)      print(10/0)
4)  except ZeroDivisionError:
5)      print("except")
6)  finally:
7)      print("finally")
8)
9)  Output
10) try
11) except
12) finally
```

Case-3: **If there is an exception raised but not handled:**

```
1)  try:
2)      print("try")
3)      print(10/0)
4)  except NameError:
5)      print("except")
6)  finally:
7)      print("finally")
8)
9)  Output
10) try
11) finally
12) ZeroDivisionError: division by zero(Abnormal Termination)
```

*** Note: **There is only one situation where finally block won't be executed ie wheneverwe are using os._exit(0) function.**

Whenever we are using os._exit(0) function then Python Virtual Machine itself will beshutdown.In this particular case finally won't be executed.

```
1)   imports
2)  try:
3)      print("try")
4)      os._exit(0)
5)  except NameError:
6)      print("except")
7)  finally:
8)      print("finally")
9)
10) Output
11) try
```

Note:
os._exit(0)
   where 0 represents status code and it indicates normal termination
   There are multiple status codes are possible.

Control flow in try-except-finally:

```
try:
   stmt-1
   stmt-2
   stmt-3
except:
   stmt-4
```

finally:
   stmt-5
stmt6

Case-1: If there is no exception1,2,3,5,6 Normal Termination

Case-2: If an exception raised at stmt2 and the corresponding except block matched 1,4,5,6 Normal Termination

Case-3: If an exception raised at stmt2 but the corresponding except block not matched 1,5 Abnormal Termination

Case-4:If an exception raised at stmt4 then it is always abnormal termination but beforethat finally block will be executed.

Case-5: If an exception raised at stmt-5 or at stmt-6 then it is always abnormaltermination

Nested try-except-finally blocks:

We can take try-except-finally blocks inside try or except or finally blocks.i.e nesting of try-except-finally is possible.

```
try
:     ----------
      ----------
      ----------
   try:
      ------------
         -------------
         -------------
   except:
      --------------
      --------------
      --------------
   ------------
except:
      -----------
      -----------
      -----------
```
General Risky code we have to take inside outer try block and too much risky code we have to take inside inner try block. Inside Inner try block if an exception raised then inner

except block is responsible to handle. If it is unable to handle then outer except block isresponsible to handle.

Eg:

```
1)  try:
2)      print("outer try block")
3)      try:
4)          print("Inner try block")
5)          print(10/0)
6)      except ZeroDivisionError:
7)          print("Inner except block")
8)      finally:
9)          print("Inner finally block")
10) except:
11)     print("outer except block")
12) finally:
13)     print("outer finally block")
14)
15) Output
16) outer try block
17) Inner try block
18) Inner except block
19) Inner finally block
20) outer finally block
```

Control flow in nested try-except-finally:

```
try
:       stmt-1
        stmt-2
        stmt-3
        try:
                stmt-4
                stmt-5
                stmt-6
        except X:
                stmt-7
        finally
:               stmt-8

        stmt-9
except Y:
        stmt-10
finally
:       stmt-11
stmt-12
```

case-1: **If there is no exception**
1,2,3,4,5,6,8,9,11,12 Normal
Termination

case-2: **If an exception raised at stmt-2 and the corresponding except block matched**
1,10,11,12 Normal Termination

case-3: **If an exceptiion raised at stmt-2 and the corresponding except block not**
matched1,11,Abnormal Termination

case-4: **If an exception raised at stmt-5 and inner except block matched**
1,2,3,4,7,8,9,11,12 Normal Termination

case-5: **If an exception raised at stmt-5 and inner except block not matched but outer**
except block matched

1,2,3,4,8,10,11,12,Normal Termination

case-6: **If an exception raised at stmt-5 and both inner and outer except blocks are not**
matched

1,2,3,4,8,11,Abnormal Termination

case-7: **If an exception raised at stmt-7 and corresponding except block matched**
1,2,3,.,.,.,8,10,11,12,Normal Termination

case-8: **If an exception raised at stmt-7 and corresponding except block not matched**
1,2,3,.,.,.,8,11,Abnormal Termination

case-9: **If an exception raised at stmt-8 and corresponding except block matched**
1,2,3,.,.,.,.,10,11,12 Normal Termination

case-10: **If an exception raised at stmt-8 and corresponding except block not matched**
1,2,3,.,.,.,.,11,Abnormal Termination

case-11: **If an exception raised at stmt-9 and corresponding except block matched**
1,2,3,.,.,.,.,8,10,11,12,Normal Termination

case-12: **If an exception raised at stmt-9 and corresponding except block not matched**
1,2,3,.,.,.,.,8,11,Abnormal Termination

case-13: **If an exception raised at stmt-10 then it is always abonormal termination but**
before abnormal termination finally block(stmt-11) will be executed.

case-14: If an exception raised at stmt-11 or stmt-12 then it is always abnormal termination.

Note: If the control entered into try block then compulsary finally block will be executed.If the control not entered into try block then finally block won't be executed.

else block with try-except-finally:

We can use else block with try-except-finally blocks.
else block will be executed if and only if there are no exceptions inside try block.

try:
    Risky Code
except:
    will be executed if exception inside try
else:
    will be executed if there is no exception inside try
finally
    will be executed whether exception raised or not raised and handled or not
:

handled

Eg:

try
:   print("try")
    print(10/0)--->1
except:
    print("except")
else:
    print("else")
finally
    print("finally
:
    ")

If we comment line-1 then else block will be executed b'z there is no exception inside try.In this case the output is:

try
else
finall
y

If we are not commenting line-1 then else block won't be executed b'z there is exception inside try block. In this case output is:

try
except
finally

Various possible combinations of try-except-else-finally:

1. Whenever we are writing try block, compulsory we should write except or finallyblock.i.e without except or finally block we cannot write try block.

2. Wheneever we are writing except block, compulsory we should write try block. i.eexcept without try is always invalid.

3. Whenever we are writing finally block, compulsory we should write try block. i.e finallywithout try is always invalid.

4. We can write multiple except blocks for the same try,but we cannot write multiplefinally blocks for the same try

5. Whenever we are writing else block compulsory except block should be there. i.ewithout except we cannot write else block.

6. In try-except-else-finally order is important.

7. We can define try-except-else-finally inside try,except,else and finally blocks. i.e nestingof try-except-else-finally is always possible.

	      print("except")
	finally:
	      print("finally")
		☐

Types of Exceptions:

In Python there are 2 types of exceptions are possible.
1. Predefined Exceptions
2. User Definded Exceptions

1. Predefined Exceptions:

Also known as in-built exceptions

The exceptions which are raised automatically by Python virtual machine whenver aparticular event occurs, are called pre defined exceptions.

Eg 1: Whenever we are trying to perform Division by zero, automatically Python will raiseZeroDivisionError.
   print(10/0)

Eg 2: Whenever we are trying to convert input value to int type and if input value is notint value then Python will raise ValueError automatically

x=int("ten")===>ValueError

2. User Defined Exceptions:

Also known as Customized Exceptions or Programatic Exceptions

Some time we have to define and raise exceptions explicitly to indicate that somethinggoes wrong ,such type of exceptions are called User Defined Exceptions or Customized Exceptions

Programmer is responsible to define these exceptions and Python not having any idea about these. Hence we have to raise explicitly based on our requirement by using "raise" keyword.

Eg:
InSufficientFundsException
InvalidInputException
TooYoungException
TooOldException

How to Define and Raise Customized Exceptions:

Every exception in Python is a class that extends Exception class either directly orindirectly.

Syntax:
  class classname(predefined exception class
     name):def__init_(self,arg):
          self.msg=arg

Eg:

```
1)  class TooYoungException(Exception):
2)    def__init_(self,arg):
3)      self.msg=arg
```

TooYoungException is our class name which is the child class of Exception

We can raise exception by using raise keyword as follows
raise TooYoungException("message")

Eg:

```
1)   class TooYoungException(Exception):
2)     def__init_(self,arg):
3)       self.msg=arg
4)
5)   class TooOldException(Exception):
6)     def__init_(self,arg):
7)       self.msg=arg
8)
9)   age=int(input("Enter Age:"))
10)  if age>60:
11)    raise TooYoungException("Plz wait some more time you will get best match soon!!!")
12)  elif age<18:
13)    raise TooOldException("Your age already crossed marriage age...no chance of getting ma
       rriage")
14)  else:
15)    print("You will get match details soon by email!!!")
16)
17)  D:\Python_classes>py test.py
```

18) Enter Age:90
19) __main__.TooYoungException: Plz wait some more time you will get best match soon!!!
20)
21) D:\Python_classes>py test.py
22) Enter Age:12
23) __main__.TooOldException: Your age already crossed marriage age...no chance of g
24) etting marriage
25)
26) D:\Python_classes>py test.py
27) Enter Age:27
28) You will get match details soon by email!!!

Note:
raise keyword is best suitable for customized exceptions but not for pre definedexceptions

PYTHON LOGGING

Logging the Exceptions:

It is highly recommended to store complete application flow and exceptions information to a file. This process is called logging.

The main advantages of logging are:

1. We can use log files while performing debugging
2. We can provide statistics like number of requests per day etc
To implement logging, Python provides one inbuilt module logging.

logging levels:

Depending on type of information, logging data is divided according to the following 6levels in Python.
  table

 1. CRITICAL==>50==>Represents a very serious problem that needs high attention
 2. ERROR===>40===>Represents a serious error
 3. WARNING==>30==>Represents a warning message, some caution needed. It is alert tothe programmer
4. INFO===>20===>Represents a message with some important information
5. DEBUG===>10==>Represents a message with debugging information
6. NOTSET==>0==>Rrepresents that the level is not set.

By default while executing Python program only WARNING and higher level messages willbe displayed.

How to implement logging:

To perform logging, first we required to create a file to store messages and we have to specify which level messages we have to store.

We can do this by using basicConfig() function of logging module.

logging.basicConfig(filename='log.txt',level=logging.WARNING)

The above line will create a file log.txt and we can store either WARNING level or higherlevel messages to that file.

After creating log file, we can write messages to that file by using the following methods.

logging.debug(message)
logging.info(message)
logging.warning(message)
logging.error(message)
logging.critical(message)

Q.Write a Python program to create a log file and write WARNING and higherlevel messages?

```
1)  import logging
2)  logging.basicConfig(filename='log.txt',level=logging.WARNING)
3)  print("Logging Module Demo")
4)  logging.debug("This is debug message")
5)  logging.info("This is info message")
6)  logging.warning("This is warning message")
7)  logging.error("This is error message")
8)  logging.critical("This is critical message")
```

log.txt:

```
1)  WARNING:root:This is warning message
2)  ERROR:root:This is error message
3)  CRITICAL:root:This is critical message
```

Note:
In the above program only WARNING and higher level messages will be written to log file.If we set level as DEBUG then all messages will be written to log file.

```
1)  import logging
2)  logging.basicConfig(filename='log.txt',level=logging.DEBUG)
3)  print("Logging Module Demo")
4)  logging.debug("This is debug message")
5)  logging.info("This is info message")
6)  logging.warning("This is warning message")
7)  logging.error("This is error message")
8)  logging.critical("This is critical message")
```

log.txt:

```
1)  DEBUG:root:This is debug message
2)  INFO:root:This is info message
```

3) **WARNING:root:This is warning message**
4) **ERROR:root:This is error message**
5) **CRITICAL:root:This is critical message**

<u>**Note:**</u> **We can format log messages to include date and time, ip address of the client etcat advanced level.**

How to write Python program exceptions to the log file:

By using the following function we can write exceptions information to the log file.

logging.exception(msg)

Q. Python Program to write exception information to the log file

```
1)  import logging
2)  logging.basicConfig(filename='mylog.txt',level=logging.INFO)
3)  logging.info("A New request Came:")
4)  try:
5)      x=int(input("Enter First Number: "))
6)      y=int(input("Enter Second Number: "))
7)      print(x/y)
8)  except ZeroDivisionError as msg:
9)      print("cannot divide with zero")
10)     logging.exception(msg)
11) except ValueError as msg:
12)     print("Enter only int values")
13)     logging.exception(msg)
14) logging.info("Request Processing Completed")
15)
16)
17) D:\Python_classes>py test.py
18) Enter First Number: 10
19) Enter Second Number: 2
20) 5.0
21)
22) D:\Python_classes>py test.py
23) Enter First Number: 10
24) Enter Second Number: 0
25) cannot divide with zero
26)
27) D:\Python_classes>py test.py
28) Enter First Number: 10
29) Enter Second Number: ten
30) Enter only int values
```

mylog.txt:

1) INFO:root:A New request Came:
2) INFO:root:Request Processing Completed
3) INFO:root:A New request Came:
4) ERROR:root:division by zero
5) Traceback (most recent call last):
6)   File "test.py", line 7, in <module>
7)   print(x/y)
8) ZeroDivisionError: division by zero
9) INFO:root:Request Processing Completed
10) INFO:root:A New request Came:
11) ERROR:root:invalid literal for int() with base 10: 'ten'
12) Traceback (most recent call last):
13)   File "test.py", line 6, in <module>
14)   y=int(input("Enter Second Number: "))
15) ValueError: invalid literal for int() with base 10: 'ten'
16) INFO:root:Request Processing Completed

PYTHON DEBUGGING BY USING ASSERTIONS

Debugging Python Program by using assert keyword:

The process of identifying and fixing the bug is called debugging.
Very common way of debugging is to use print() statement. But the problem with the print() statement is after fixing the bug,compulsory we have to delete the extra added print() statments,otherwise these will be executed at runtime which creates performance problems and disturbs console output.

To overcome this problem we should go for assert statement. The main advantage of assert statement over print() statement is after fixing bug we are not required to delete assert statements. Based on our requirement we can enable or disable assert statements.

Hence the main purpose of assertions is to perform debugging. Usully we can perform debugging either in development or in test environments but not in production environment. Hence assertions concept is applicable only for dev and test environments but not for production environment.

Types of assert statements:

There are 2 types of assert statements

1. Simple Version
2. Augmented Version

1. Simple Version:

assert conditional_expression

2. Augmented Version:

assert conditional_expression,message

conditional_expression will be evaluated and if it is true then the program will becontinued.
If it is false then the program will be terminated by raising AssertionError.
By seeing AssertionError, programmer can analyze the code and can fix the

problem.**Eg:**

```
1)  def squareIt(x):
2)     return x**x
```

```
 3)  assert squareIt(2)==4,"The square of 2 should be 4"
 4)  assert squareIt(3)==9,"The square of 3 should be 9"
 5)  assert squareIt(4)==16,"The square of 4 should be 16"
 6)  print(squareIt(2))
 7)  print(squareIt(3))
 8)  print(squareIt(4))
 9)
10)  D:\Python_classes>py test.py
11)  Traceback (most recent call last):
12)   File "test.py", line 4, in <module>
13)     assert squareIt(3)==9,"The square of 3 should be 9"
14)  AssertionError: The square of 3 should be 9
15)
16)  def squareIt(x):
17)     return x*x
18)  assert squareIt(2)==4,"The square of 2 should be 4"
19)  assert squareIt(3)==9,"The square of 3 should be 9"
20)  assert squareIt(4)==16,"The square of 4 should be 16"
21)  print(squareIt(2))
22)  print(squareIt(3))
23)  print(squareIt(4))
24)
25)  Output
26)  4
27)  9
28)  16
```

Exception Handling vs Assertions:

Assertions concept can be used to alert programmer to resolve development time errors.

Exception Handling can be used to handle runtime errors.

Python's Object Oriented Programming (OOPs)

What is Class:

⚽ In Python every thing is an object. To create objects we required some Model or Plan or Blueprint, which is nothing but class.

⚽ We can write a class to represent properties (attributes) and actions (behaviour) of object.

⚽ Properties can be represented by variables

⚽ Actions can be represented by Methods.

⚽ Hence class contains both variables and methods.

How to Define a class?

We can define a class by using class keyword.

Syntax:
class className:
  ''' documenttation string '''
   variables:instance variables,static and local variables
   methods: instance methods,static methods,class methods

Documentation string represents description of the class. Within the class doc string is always optional. We can get doc string by using the following 2 ways.

1. print(classname.__doc__)
2. help(classname)

Example:

```
1) class Student:
2)    """ This is student class with required data'''
3)  print(Student.__doc__)
4) help(Student)
```

Within the Python class we can represent data by using variables.There are 3 types of variables are allowed.

1. Instance Variables (Object Level Variables)
2. Static Variables (Class Level Variables)
3. Local variables (Method Level Variables)

Within the Python class, we can represent operations by using methods. The following are varioustypes of allowed methods

1. Instance Methods
2. Class Methods
3. Static Methods

Example for class:

```
1) class Student:
2)     """Developed by durga for python demo'''
3)     def __init__(self):
4)         self.name='durga'
5)         self.age=40
6)         self.marks=80
7)
8)     def talk(self):
9)         print("Hello I am :",self.name)
10)         print("My Age is:",self.age)
11)         print("My Marks are:",self.marks)
```

What is Object:

Pysical existence of a class is nothing but object. We can create any number of objects for a class.

Syntax to create object: referencevariable = classname()

Example: s = Student()

What is Reference Variable:

The variable which can be used to refer object is called reference variable.
By using reference variable, we can access properties and methods of
object.

Program: Write a Python program to create a Student class and Creates an object to it. Call the method talk() to display student details

```
1)  class Student:
2)
3)      def __init__(self,name,rollno,marks):
4)          self.name=name
5)          self.rollno=rollno
6)          self.marks=marks
7)
8)      def talk(self):
9)          print("Hello My Name is:",self.name)
10)         print("My Rollno is:",self.rollno)
11)         print("My Marks are:",self.marks)
12)
```

13) s1=Student(**"Durga"**,101,80)
14) s1.talk()

Output:
D:\durgaclasses>py
test.pyHello My Name is:
Durga My Rollno is: 101
My Marks are: 80

Self variable:

self is the default variable which is always pointing to current object (like this keyword in

Java)By using self we can access instance variables and instance methods of object.

Note:
1. self should be first parameter inside
   constructordef__init_(self):

2. self should be first parameter inside instance
   methodsdef talk(self):

Constructor Concept:
- Constructor is a special method in python.
- The name of the constructor should be __init__(self)
- Constructor will be executed automatically at the time of object creation.
- The main purpose of constructor is to declare and initialize instance variables.
- Per object constructor will be exeucted only once.
- Constructor can take atleast one argument(atleast self)
- Constructor is optional and if we are not providing any constructor then python will providedefault constructor.

Example:

```
1)  def __init__(self,name,rollno,marks):
2)       self.name=name
3)       self.rollno=rollno
4)       self.marks=marks
```

Program to demonistrate constructor will execute only once per object:

```
1) class Test:
2)
3)   def__init_(self):
4)     print("Constructor exeuction...")
5)
```

```
6)     def m1(self):
7)        print("Method execution...")
8)
9)  t1=Test()
10) t2=Test()
11) t3=Test()
12) t1.m1()
```

Output
Constructor
exeuction...
Constructor
exeuction...
Constructor
exeuction...   Method
execution...

Program:

```
1)  class Student:
2)
3)     ''' This is student class with required data'''
4)     def __init__(self,x,y,z):
5)        self.name=x
6)        self.rollno=y
7)        self.marks=z
8)
9)     def display(self):
10)       print("Student Name:{}\nRollno:{} \nMarks:{}".format(self.name,self.rollno,self.marks)
    )
11)
12) s1=Student("Durga",101,80)
13) s1.display()
14) s2=Student("Sunny",102,100)
15) s2.display()
```

Output
Student
Name:Durga
Rollno:101
Marks:80
Student
Name:Sunny
Rollno:102
Marks:100

Differences between Methods and Constructors:

Method	Constructor
1. Name of method can be any name	1. Constructor name should be always __init__
2. Method will be executed if we call that method	2. Constructor will be executed automatically at the time of object creation.
3. Per object, method can be called any number of times.	3. Per object, Constructor will be executed only once
4. Inside method we can write business logic	4. Inside Constructor we have to declare and initialize instance variables

Types of Variables:

Inside Python class 3 types of variables are allowed.

1. Instance Variables (Object Level Variables)
2. Static Variables (Class Level Variables)
3. Local variables (Method Level Variables)

1. Instance Variables:

If the value of a variable is varied from object to object, then such type of variables are calledinstance variables.

For every object a separate copy of instance variables will be created.

Where we can declare Instance variables:
1. Inside Constructor by using self variable
2. Inside Instance Method by using self variable
3. Outside of the class by using object reference variable

1. Inside Constructor by using self variable:
We can declare instance variables inside a constructor by using self keyword. Once we createsobject, automatically these variables will be added to the object.

Example:

```python
1)  class Employee:
2)
3)      def __init__(self):
4)          self.eno=100
5)          self.ename='Durga'
6)          self.esal=10000
7)
8)  e=Employee()
```

```
9)  print(e.__dict__)
```

Output: {'eno': 100, 'ename': 'Durga', 'esal': 10000}

2. Inside Instance Method by using self variable:

We can also declare instance variables inside instance method by using self variable. If any instance variable declared inside instance method, that instance variable will be added once wecall taht method.

Example:

```
1)  class Test:
2)
3)      def __init__(self):
4)          self.a=10
5)          self.b=20
6)
7)      def m1(self):
8)          self.c=30
9)
10) t=Test()
11) t.m1()
12) print(t.__dict__)
```

Output
{'a': 10, 'b': 20, 'c': 30}

3. Outside of the class by using object reference variable:
We can also add instance variables outside of a class to a particular object.

```
1)  class Test:
2)
3)      def __init__(self):
4)          self.a=10
5)          self.b=20
6)
7)      def m1(self):
8)          self.c=30
9)
10) t=Test()
11) t.m1()
12) t.d=40
13) print(t.__dict__)
```

Output {'a': 10, 'b': 20, 'c': 30, 'd': 40}

How to access Instance variables:

We can access instance variables with in the class by using self variable and outside of the class byusing object reference.

```
1)  class Test:
2)
3)      def __init__(self):
4)          self.a=10
5)          self.b=20
6)
7)      def display(self):
8)          print(self.a)
9)          print(self.b)
10)
11) t=Test()
12) t.display()
13) print(t.a,t.b)
```

Output
10
20
10 20

How to delete instance variable from the object:

1. Within a class we can delete instance variable as follows

del self.variableName

2. From outside of class we can delete instance variables as follows

del objectreference.variableName

Example:

```
1)   class Test:
2)       def __init__(self):
3)           self.a=10
4)           self.b=20
5)           self.c=30
6)           self.d=40
7)       def m1(self):
8)           del self.d
9)
10)  t=Test()
11)  print(t.__dict__)
```

```
12) t.m1()
13) print(t.__dict__)
14) del t.c
15) print(t.__dict__)
```

Output
{'a': 10, 'b': 20, 'c': 30, 'd': 40}
{'a': 10, 'b': 20, 'c': 30}
{'a': 10, 'b': 20}

<u>Note:</u> **The instance variables which are deleted from one object,will not be deleted from other objects.**

<u>Example:</u>

```
1)  class Test:
2)    def __init__(self):
3)        self.a=10
4)        self.b=20
5)        self.c=30
6)        self.d=40
7)
8)
9)  t1=Test()
10) t2=Test()
11) del t1.a
12) print(t1.__dict__)
13) print(t2.__dict__)
```

Output
{'b': 20, 'c': 30, 'd': 40}
{'a': 10, 'b': 20, 'c': 30, 'd': 40}

If we change the values of instance variables of one object then those changes won't be reflected to the remaining objects, because for every object we are separate copy of instance variables areavailable.

<u>Example:</u>

```
1)  class Test:
2)    def __init__(self):
3)        self.a=10
4)        self.b=20
5)
6)  t1=Test()
7)  t1.a=888
8)  t1.b=999
9)  t2=Test()
10) print('t1:',t1.a,t1.b)
```

```
11) print('t2:',t2.a,t2.b)
```

Output
t1: 888 999
t2: 10 20

1. Static variables:

If the value of a variable is not varied from object to object, such type of variables we have to declare with in the class directly but outside of methods. Such type of variables are called Staticvariables.

For total class only one copy of static variable will be created and shared by all objects of that class.

We can access static variables either by class name or by object reference. But recommended to use class name.

Instance Variable vs Static Variable:

Note: In the case of instance variables for every object a seperate copy will be created,but in the case of static variables for total class only one copy will be created and shared by every object ofthat class.

```
1)  class Test:
2)      x=10
3)      def___init_(self):
4)          self.y=20
5)
6)  t1=Test()
7)  t2=Test()
8)  print('t1:',t1.x,t1.y)
9)  print('t2:',t2.x,t2.y)
10) Test.x=888
11) t1.y=999
12) print('t1:',t1.x,t1.y)
13) print('t2:',t2.x,t2.y)
```

Output
t1: 10 20
t2: 10 20
t1: 888 999
t2: 888 20

Various places to declare static variables:

1. In general we can declare within the class directly but from out side of any method
2. Inside constructor by using class name
3. Inside instance method by using class name
4. Inside classmethod by using either class name or cls variable
5. Inside static method by using class name

```
1)  class Test:
2)      a=10
3)      def __init__(self):
4)          Test.b=20
5)      def m1(self):
6)          Test.c=30
7)      @classmethod
8)      def m2(cls):
9)          cls.d1=40
10)         Test.d2=400
11)     @staticmethod
12)     def m3():
13)         Test.e=50
14) print(Test.__dict__)
15) t=Test()
16) print(Test.__dict__)
17) t.m1()
18) print(Test.__dict__)
19) Test.m2()
20) print(Test.__dict__)
21) Test.m3()
22) print(Test.__dict__)
23) Test.f=60
24) print(Test.__dict__)
```

How to access static variables:

1. inside constructor: by using either self or classname
2. inside instance method: by using either self or classname
3. inside class method: by using either cls variable or classname
4. inside static method: by using classname
5. From outside of class: by using either object reference or classnmae

```
1)  class Test:
2)      a=10
3)      def __init__(self):
4)          print(self.a)
5)          print(Test.a)
6)      def m1(self):
7)          print(self.a)
```

```python
8)        print(Test.a)
9)     @classmethod
10)    def m2(cls):
11)        print(cls.a)
12)        print(Test.a)
13)    @staticmethod
14)    def m3():
15)        print(Test.a)
16) t=Test()
17) print(Test.a)
18) print(t.a)
19) t.m1()
20) t.m2()
21) t.m3()
```

Where we can modify the value of static variable:

Anywhere either with in the class or outside of class we can modify by using classname.But inside class method, by using cls variable.

Example:

```python
1)  class Test:
2)      a=777
3)      @classmethod
4)      def m1(cls):
5)          cls.a=888
6)      @staticmethod
7)      def m2():
8)          Test.a=999
9)  print(Test.a)
10) Test.m1()
11) print(Test.a)
12) Test.m2()
13) print(Test.a)
```

Output
777
888
999

*****

If we change the value of static variable by using either self or object reference variable:

If we change the value of static variable by using either self or object reference variable, then the value of static variable won't be changed, just a new instance variable with that name will be added to that particular object.

Example 1:

```
1)  class Test:
2)    a=10
3)    def m1(self):
4)      self.a=888
5)  t1=Test()
6)  t1.m1()
7)  print(Test.a)
8)  print(t1.a)
```

Output
10
888

Example:

```
1)  class Test:
2)    x=10
3)    def __init__(self):
4)      self.y=20
5)
6)  t1=Test()
7)  t2=Test()
8)  print('t1:',t1.x,t1.y)
9)  print('t2:',t2.x,t2.y)
10) t1.x=888
11) t1.y=999
12) print('t1:',t1.x,t1.y)
13) print('t2:',t2.x,t2.y)
```

Output
t1: 10 20
t2: 10 20
t1: 888 999
t2: 10 20

Example:

```
1)  class Test:
2)      a=10
3)      def __init__(self):
4)          self.b=20
5)  t1=Test()
6)  t2=Test()
7)  Test.a=888
8)  t1.b=999
9)  print(t1.a,t1.b)
10) print(t2.a,t2.b)
```

Output
888 999
888 20

```
1)  class Test:
2)      a=10
3)      def __init__(self):
4)          self.b=20
5)      def m1(self):
6)          self.a=888
7)          self.b=999
8)
9)  t1=Test()
10) t2=Test()
11) t1.m1()
12) print(t1.a,t1.b)
13) print(t2.a,t2.b)
```

Output
888 999
10 20

Example:

```
1)  class Test:
2)      a=10
3)      def __init__(self):
4)          self.b=20
5)      @classmethod
6)      def m1(cls):
7)          cls.a=888
8)          cls.b=999
9)
10) t1=Test()
11) t2=Test()
```

```
12) t1.m1()
13) print(t1.a,t1.b)
14) print(t2.a,t2.b)
15) print(Test.a,Test.b)
```

Output
888 20
888 20
888 999

How to delete static variables of a class:

We can delete static variables from anywhere by using the following syntax

`del  classname.variablename`

But inside classmethod we can also use cls variable

`del  cls.variablename`

```
1) class Test:
2)    a=10
3)    @classmethod
4)    def m1(cls):
5)       del cls.a
6) Test.m1()
7) print(Test.__dict__)
```

Example:

```
1)  class Test:
2)     a=10
3)     def __init__(self):
4)        Test.b=20
5)        del Test.a
6)     def m1(self):
7)        Test.c=30
8)        del Test.b
9)     @classmethod
10)    def m2(cls):
11)       cls.d=40
12)       del Test.c
13)    @staticmethod
14)    def m3():
15)       Test.e=50
16)       del Test.d
17) print(Test.__dict__)
18) t=Test()
```

```
19) print(Test.__dict__)
20) t.m1()
21) print(Test.__dict__)
22) Test.m2()
23) print(Test.__dict__)
24) Test.m3()
25) print(Test.__dict__)
26) Test.f=60
27) print(Test.__dict__)
28) del Test.e
29) print(Test.__dict__)
```

****

Note: By using object reference variable/self we can read static variables, but we cannot modify or delete.

If we are trying to modify, then a new instance variable will be added to that particular object. t1.a = 70

 If we are trying to delete then we will get error.

Example:

```
1)  class Test:
2)     a=10
3)
4) t1=Test()
5)  del t1.a     ===>AttributeError: a
```

We can modify or delete static variables only by using classname or cls variable.

```
1)  import sys
2)  class Customer:
3)      ''' Customer class with bank operations.. '''
4)      bankname='DURGABANK'
5)      def __init__(self,name,balance=0.0):
6)          self.name=name
7)          self.balance=balance
8)      def deposit(self,amt):
9)          self.balance=self.balance+amt
10)         print('Balance after deposit:',self.balance)
11)     def withdraw(self,amt):
12)         if amt>self.balance:
13)             print('Insufficient Funds..cannot perform this operation')
14)             sys.exit()
15)         self.balance=self.balance-amt
16)         print('Balance after withdraw:',self.balance)
17)
18) print('Welcome to',Customer.bankname)
```

```python
19)  name=input('Enter Your Name:')
20)  c=Customer(name)
21)  while True:
22)      print('d-Deposit \nw-Withdraw \ne-exit')
23)      option=input('Choose your option:')
24)      if option=='d' or option=='D':
25)          amt=float(input('Enter amount:'))
26)          c.deposit(amt)
27)      elif option=='w' or option=='W':
28)          amt=float(input('Enter amount:'))
29)          c.withdraw(amt)
30)      elif option=='e' or option=='E':
31)          print('Thanks for Banking')
32)          sys.exit()
33)      else:
34)          print('Invalid option..Plz choose valid option')
```

output:

Local variables:

Sometimes to meet temporary requirements of programmer,we can declare variables inside amethod directly,such type of variables are called local variable or temporary variables.

Local variables will be created at the time of method execution and destroyed once methodcompletes.

Local variables of a method cannot be accessed from outside of method.

Example:

```python
1)   class Test:
2)     def m1(self):
3)        a=1000
4)        print(a)
5)     def m2(self):
6)        b=2000
7)        print(b)
8)  t=Test()
9)  t.m1()
10) t.m2()
```

Output
1000
2000

Example 2:

```python
1)   class Test:
2)     def m1(self):
3)        a=1000
4)        print(a)
5)     def m2(self):
6)        b=2000
7)        print(a)    #NameError: name 'a' is not defined
8)        print(b)
9)  t=Test()
10) t.m1()
11) t.m2()
```

Types of Methods:

Inside Python class 3 types of methods are allowed

1. Instance Methods
2. Class Methods
3. Static Methods

1. Instance Methods:

Inside method implementation if we are using instance variables then such type of methods arecalled instance methods.
Inside instance method declaration,we have to pass self variable.

`def m1(self):`

By using self variable inside method we can able to access instance variables.

Within the class we can call instance method by using self variable and from outside of the classwe can call by using object reference.

```python
1)  class Student:
2)     def __init__(self,name,marks):
3)        self.name=name
4)        self.marks=marks
5)     def display(self):
6)        print('Hi',self.name)
7)        print('Your Marks are:',self.marks)
8)     def grade(self):
9)        if self.marks>=60:
10)          print('You got First Grade')
11)       elif self.marks>=50:
12)          print('Yout got Second Grade')
13)       elif self.marks>=35:
14)          print('You got Third Grade')
15)       else:
16)          print('You are Failed')
17) n=int(input('Enter number of students:'))
18) for i in range(n):
19)    name=input('Enter Name:')
20)    marks=int(input('Enter Marks:'))
21)    s= Student(name,marks)
22)    s.display()
23)    s.grade()
24)    print()
```

ouput:
D:\durga_classes>py
test.py Enter number of
students:2   Enter
Name:Durga
Enter
Marks:90Hi
Durga
Your Marks are: 90
You got First Grade

Enter
Name:Ravi
Enter Marks:12
Hi Ravi
Your Marks are:
12You are Failed

Setter and Getter Methods:

We can set and get the values of instance variables by using getter and setter methods.

Setter Method:

setter methods can be used to set values to the instance variables. setter methods also known as mutator methods.

syntax:

def setVariable(self,variable):
    self.variable=variable

Example:
def setName(self,name):
    self.name=name

Getter Method:

Getter methods can be used to get values of the instance variables. Getter methods also known asaccessor methods.

syntax:

def getVariable(self):
    return
    self.variable

Example:
def getName(self):
    return
    self.name

Demo Program:

```python
1) class Student:
2)     def setName(self,name):
3)        self.name=name
4)
5)     def getName(self):
6)        return self.name
7)
8)     def setMarks(self,marks):
9)        self.marks=marks
10)
11)    def getMarks(self):
12)       return self.marks
13)
14) n=int(input('Enter number of students:'))
15) for i in range(n):
16)    s=Student()
17)    name=input('Enter Name:')
18)    s.setName(name)
19)    marks=int(input('Enter Marks:'))
20)    s.setMarks(marks)
21)
22)    print('Hi',s.getName())
23)    print('Your Marks are:',s.getMarks())
24)    print()
```

output:
D:\python_classes>py test.py
Enter number of students:2
Enter Name:Durga
Enter
Marks:100Hi
Durga
Your Marks are: 100

Enter
Name:Ravi
Enter Marks:80
Hi Ravi
Your Marks are: 80

2. Class Methods:

Inside method implementation if we are using only class variables (static variables), then such typeof methods we should declare as class method.

We can declare class method explicitly by using @classmethod decorator.For class method we should provide cls variable at the time of declaration

We can call classmethod by using classname or object reference variable.

Demo Program:

```
1)  class Animal:
2)      legs=4
3)      @classmethod
4)      def walk(cls,name):
5)          print('{} walks with {} legs...'.format(name,cls.legs))
6)  Animal.walk('Dog')
7)  Animal.walk('Cat')
```

Output
D:\python_classes>py test.py
Dog walks with 4 legs...
Cat walks with 4 legs...

Program to track the number of objects created for a class:

```
1)  class Test:
2)      count=0
3)      def __init__(self):
4)          Test.count =Test.count+1
5)      @classmethod
6)      def noOfObjects(cls):
7)          print('The number of objects created for test class:',cls.count)
8)
9)  t1=Test()
10) t2=Test()
11) Test.noOfObjects()
12) t3=Test()
13) t4=Test()
14) t5=Test()
15) Test.noOfObjects()
```

3. Static Methods:

In general these methods are general utility methods.
Inside these methods we won't use any instance or class variables.
Here we won't provide self or cls arguments at the time of
declaration.

We can declare static method explicitly by using @staticmethod decorator
We can access static methods by using classname or object reference

```
1)  class DurgaMath:
2)
3)      @staticmethod
4)      def add(x,y):
```

```
5)        print('The Sum:',x+y)
6)
7)    @staticmethod
8)    def product(x,y):
9)        print('The Product:',x*y)
10)
11)   @staticmethod
12)   def average(x,y):
13)       print('The average:',(x+y)/2)
14)
15) DurgaMath.add(10,20)
16) DurgaMath.product(10,20)
17) DurgaMath.average(10,20)
```

Output
The Sum: 30
The Product: 200
The average: 15.0

Note: In general we can use only instance and static methods.Inside static method we can access class level variables by using class name.

class methods are most rarely used methods in python.

Passing members of one class to another class:

We can access members of one class inside another class.

```
1)  class Employee:
2)    def __init__(self,eno,ename,esal):
3)        self.eno=eno
4)        self.ename=ename
5)        self.esal=esal
6)    def display(self):
7)        print('Employee Number:',self.eno)
8)        print('Employee Name:',self.ename)
9)        print('Employee Salary:',self.esal)
10) class Test:
11)   def modify(emp):
12)       emp.esal=emp.esal+10000
13)       emp.display()
14) e=Employee(100,'Durga',10000)
15)  Test.modify(e)
```

Output
D:\python_classes>py test.py
Employee Number: 100
Employee Name: Durga

Employee Salary: 20000

In the above application, Employee class members are available to Test class.

Inner classes:

Sometimes we can declare a class inside another class,such type of classes are called inner classes.

Without existing one type of object if there is no chance of existing another type of object,then weshould go for inner classes.

Example: Without existing Car object there is no chance of existing Engine object. Hence Engineclass should be part of Car class.

```
class
Car:
 .....
 class Engine:
 ......
```

Example: Without existing university object there is no chance of existing Department object

```
class University:
   .....
   class Department:
   ......
```

eg3:
Without existing Human there is no chance of existin Head. Hence Head should be part of Human.

```
class Human:
   class Head:
```

Note: Without existing outer class object there is no chance of existing inner class object. Hence inner class object is always associated with outer class object.

Demo Program-1:

```
1)  class Outer:
2)    def __init__(self):
3)      print("outer class object creation")
4)    class Inner:
5)      def __init__(self):
6)        print("inner class object creation")
7)      def m1(self):
8)        print("inner class method")
9)  o=Outer()
10) i=o.Inner()
11) i.m1()
```

Output
outer   class   object
creationinner class object
creation   inner   class
method

Note: The following are various possible syntaxes for calling inner class

method1.
o=Outer()
i=o.Inner(
)i.m1()

2.
i=Outer().Inner
()i.m1()

3. Outer().Inner().m1()

Demo Program-2:

```
1)   class Person:
2)     def __init__(self):
3)        self.name='durga'
4)        self.db=self.Dob()
5)     def display(self):
6)        print('Name:',self.name)
7)     class Dob:
8)        def __init__(self):
9)          self.dd=10
10)         self.mm=5
11)         self.yy=1947
12)       def display(self):
13)         print('Dob={}/{}/{}'.format(self.dd,self.mm,self.yy))
14) p=Person()
15) p.display()
16) x=p.db
17) x.display()
```

Output
Name: durga
Dob=10/5/1947

Demo Program-3:

Inside a class we can declare any number of inner classes.

```
1)   class Human:
2)
3)     def __init__(self):
```

```
4)        self.name = 'Sunny'
5)        self.head = self.Head()
6)        self.brain = self.Brain()
7)    def display(self):
8)        print("Hello..",self.name)
9)
10)   class Head:
11)       def talk(self):
12)           print('Talking...')
13)
14)   class Brain:
15)       def think(self):
16)           print('Thinking...')
17)
18) h=Human()
19) h.display()
20) h.head.talk()
21) h.brain.think()
```

Output
Hello..
Sunny
Talking...
Thinking...

Garbage Collection:

In old languages like C++, programmer is responsible for both creation and destruction of objects.Usually programmer taking very much care while creating object, but neglecting destruction of useless objects. Because of his neglectance, total memory can be filled with uselessobjects which creates memory problems and total application will be down with Out of memory error.

But in Python, We have some assistant which is always running in the background to destroyuseless objects.Because this assistant the chance of failing Python program with memory problems is very less. This assistant is nothing but Garbage Collector.

Hence the main objective of Garbage Collector is to destroy useless objects.

If an object does not have any reference variable then that object eligible for Garbage Collection.

How to enable and disable Garbage Collector in our program:

By default Gargbage collector is enabled, but we can disable based on our requirement. In thiscontext we can use the following functions of gc module.

1. gc.isenabled()
   Returns True if GC enabled

2. gc.disable()
   To disable GC explicitly

3. gc.enable()
   To enable GC explicitly

Example:

```
1) import gc
2) print(gc.isenabled())
3) gc.disable()
4) print(gc.isenabled())
5) gc.enable()
6) print(gc.isenabled())
```

Outpu
tTrue
False
True

Destructors:

Destructor is a special method and the name should be __del__
Just before destroying an object Garbage Collector always calls destructor to perform clean
upactivities (Resource deallocation activities like close database connection etc).
Once destructor execution completed then Garbage Collector automatically destroys that object.

Note: The job of destructor is not to destroy object and it is just to perform clean up activities.

Example:

```
1)  import time
2)  class Test:
3)     def __init__(self):
4)         print("Object Initialization...")
5)     def __del__(self):
6)         print("Fulfilling Last Wish and performing clean up activities...")
7)
8)  t1=Test()
9)  t1=None
10) time.sleep(5)
11) print("End of application")
```

Output
Object Initialization...
Fulfilling Last Wish and performing clean up
activities...End of application

Note:
If the object does not contain any reference variable then only it is eligible fo GC. ie if thereference count is zero then only object eligible for GC

Example:

```python
1) import time
2) class Test:
3)     def __init__(self):
4)         print("Constructor Execution...")
5)     def __del__(self):
6)         print("Destructor Execution...")
7)
8) t1=Test()
9) t2=t1
10) t3=t2
11) del t1
12) time.sleep(5)
13) print("object not yet destroyed after deleting t1")
14) del t2
15) time.sleep(5)
16) print("object not yet destroyed even after deleting t2")
17) print("I am trying to delete last reference variable...")
18) del t3
```

Example:

```python
1) import time
2) class Test:
3)     def __init__(self):
4)         print("Constructor Execution...")
5)     def __del__(self):
6)         print("Destructor Execution...")
7)
8) list=[Test(),Test(),Test()]
9) del list
10) time.sleep(5)
11) print("End of application")
```

Output
Constructor
Execution...
Constructor
Execution...
Constructor
Execution...Destructor
Execution... Destructor
Execution... Destructor
Execution... End of
application

How to find the number of references of an object:

sys module contains getrefcount() function for this purpose.

sys.getrefcount(objectreference)

Example:

```
1)  import sys
2)  class Test:
3)      pass
4)  t1=Test()
5)  t2=t1
6)  t3=t1
7)  t4=t1
8)  print(sys.getrefcount(t1))
```

Output 5

Note: **For every object, Python internally maintains one default reference variable self.**

OOPs Part - 2

Using members of one class inside another class:

We can use members of one class inside another class by using the following ways

1. By Composition (Has-A Relationship)
2. By Inheritance (IS-A Relationship)

1. By Composition (Has-A Relationship):

By using Class Name or by creating object we can access members of one class inside another classis nothing but composition (Has-A Relationship).

The main advantage of Has-A Relationship is Code Reusability.

Demo Program-1:

```python
1)  class Engine:
2)      a=10
3)      def __init__(self):
4)          self.b=20
5)      def m1(self):
6)          print('Engine Specific Functionality')
7)  class Car:
8)      def __init__(self):
9)          self.engine=Engine()
10)     def m2(self):
11)         print('Car using Engine Class Functionality')
12)         print(self.engine.a)
13)         print(self.engine.b)
14)         self.engine.m1()
15) c=Car()
16) c.m2()
```

Output:
Car using Engine Class
Functionality10
20
Engine Specific Functionality

Demo Program-2:

```python
1)  class Car:
2)      def __init__(self,name,model,color):
3)          self.name=name
4)          self.model=model
5)          self.color=color
6)      def getinfo(self):
```

```python
7)         print("Car Name:{} , Model:{} and Color:{}".format(self.name,self.model,self.color))
8)
9)  class Employee:
10)    def __init__(self,ename,eno,car):
11)        self.ename=ename
12)        self.eno=eno
13)        self.car=car
14)    def empinfo(self):
15)        print("Employee Name:",self.ename)
16)        print("Employee Number:",self.eno)
17)        print("Employee Car Info:")
18)        self.car.getinfo()
19) c=Car("Innova","2.5V","Grey")
20) e=Employee('Durga',10000,c)
21) e.empinfo()
```

Output:
Employee Name: Durga
Employee Number:
10000Employee Car
Info:
Car Name: Innova, Model:2.5V and Color:Grey

In the above program Employee class Has-A Car reference and hence Employee class can access allmembers of Car class.

Demo Program-3:

```python
1)   class X:
2)     a=10
3)     def __init__(self):
4)         self.b=20
5)     def m1(self):
6)         print("m1 method of X class")
7)  class Y:
8)     c=30
9)     def __init__(self):
10)        self.d=40
11)    def m2(self):
12)        print("m2 method of Y class")
13)    def m3(self):
14)        x1=X()
15)        print(x1.a)
16)        print(x1.b)
17)        x1.m1()
18)        print(Y.c)
19)        print(self.d)
20)        self.m2()
21)        print("m3 method of Y class")
22) y1=Y()
```

```
23)  y1.m3()
```

Output:
10
20
m1 method of X
class30
40
m2 method of Y
classm3 method of Y
class

2. <u>By Inheritance(IS-A Relationship):</u>

What ever variables, methods and constructors available in the parent class by default available tothe child classes and we are not required to rewrite. Hence the main advantage of inheritance is Code Reusability and we can extend existing functionality with some more extra functionality.

<u>Syntax :</u>
class childclass(parentclass):

<u>Demo Program for inheritance:</u>

```python
1)  class P:
2)      a=10
3)      def __init__(self):
4)          self.b=10
5)      def m1(self):
6)          print('Parent instance method')
7)      @classmethod
8)      def m2(cls):
9)          print('Parent class method')
10)     @staticmethod
11)     def m3():
12)         print('Parent static method')
13)
14) class C(P):
15)     pass
16)
17) c=C()
18) print(c.a)
19) print(c.b)
20) c.m1()
21) c.m2()
22) c.m3()
```

<u>Output:</u>
10
10

Parent instance
methodParent class
method Parent static
method

Eg:

```
1)  class P:
2)      10 methods
3)  class C(P):
4)      5 methods
```

In the above example Parent class contains 10 methods and these methods automatically available to the child class and we are not required to rewrite those methods(Code Reusability)Hence child class contains 15 methods.

Note:
What ever members present in Parent class are by default available to the child class through inheritance.

Demo Program:

```
1)  class P:
2)      def m1(self):
3)          print("Parent class method")
4)  class C(P):
5)      def m2(self):
6)          print("Child class method")
7)
8)  c=C();
9)  c.m1()
10) c.m2()
```

Output:
Parent class
methodChild class
method

What ever methods present in Parent class are automatically available to the child class and henceon the child class reference we can call both parent class methods and child class methods.

Similarly variables also

```
1)  class P:
2)      a=10
3)      def __init__(self):
4)          self.b=20
5)  class C(P):
6)      c=30
7)      def __init__(self):
8)          super().__init__()===>Line-1
```

```
9)        self.d=30
10)
11) c1=C()
12) print(c1.a,c1.b,c1.c,c1.d)
```

If we comment Line-1 then variable b is not available to the child class.

Demo program for inheritance:

```python
1)  class Person:
2)     def __init__(self,name,age):
3)        self.name=name
4)        self.age=age
5)     def eatndrink(self):
6)        print('Eat Biryani and Drink Beer')
7)
8)  class Employee(Person):
9)     def __init__(self,name,age,eno,esal):
10)        super().__init__(name,age)
11)        self.eno=eno
12)        self.esal=esal
13)
14)     def work(self):
15)        print("Coding Python is very easy just like drinking Chilled Beer")
16)     def empinfo(self):
17)        print("Employee Name:",self.name)
18)        print("Employee Age:",self.age)
19)        print("Employee Number:",self.eno)
20)        print("Employee Salary:",self.esal)
21)
22) e=Employee('Durga', 48, 100, 10000)
23) e.eatndrink()
24) e.work()
25) e.empinfo()
```

Output:
Eat Biryani and Drink Beer
Coding Python is very easy just like drinking Chilled
BeerEmployee Name: Durga
Employee Age: 48
Employee Number: 100
Employee Salary: 10000

IS-A vs HAS-A Relationship:

If we want to extend existing functionality with some more extra functionality then we should go for IS-A Relationship

If we dont want to extend and just we have to use existing functionality then we should go forHAS-A Relationship

Eg: Employee class extends Person class Functionality
**   But Employee class just uses Car functionality but not extending**

```
1)   class Car:
2)      def __init__(self,name,model,color):
3)         self.name=name
4)         self.model=model
5)         self.color=color
6)      def getinfo(self):
7)         print("\tCar Name:{} \n\t Model:{} \n\t
Color:{}".format(self.name,self.model,self.col
     or))
8)
9)   class Person:
10)     def __init__(self,name,age):
11)        self.name=name
12)        self.age=age
13)     def  eatndrink(self):
14)        print('Eat Biryani and Drink Beer')
15)
16)  class Employee(Person):
17)     def __init__(self,name,age,eno,esal,car):
18)        super().__init__(name,age)
19)        self.eno=eno
20)        self.esal=esal
21)        self.car=car
22)     def work(self):
23)        print("Coding Python is very easy just like drinking Chilled Beer")
24)     def empinfo(self):
```

```
25)        print("Employee Name:",self.name)
26)        print("Employee Age:",self.age)
27)        print("Employee Number:",self.eno)
28)        print("Employee Salary:",self.esal)
29)        print("Employee Car Info:")
30)        self.car.getinfo()
31)
32) c=Car("Innova","2.5V","Grey")
33) e=Employee('Durga',48,100,10000,c)
34) e.eatndrink()
35) e.work()
36) e.empinfo()
```

Output:
Eat Biryani and Drink Beer
Coding Python is very easy just like drinking Chilled
BeerEmployee Name: Durga
Employee Age: 48
Employee Number: 100
Employee Salary:
10000Employee Car
Info:
    Car
     Name:Innova
     Model:2.5V
     Color:Grey

In the above example Employee class extends Person class functionality but just uses Car class functionality.

Composition vs Aggregation:

Composition:

Without existing container object if there is no chance of existing contained object then the container and contained objects are strongly associated and that strong association is nothing but Composition.

Eg: University contains several Departments and without existing university object there is no chance of existing Department object. Hence University and Department objects are strongly associated and this strong association is nothing but Composition.

Aggregation:

Without existing container object if there is a chance of existing contained object then the container and contained objects are weakly associated and that weak association is nothing butAggregation.

Eg: Department contains several Professors. Without existing Department still there may be a chance of existing Professor. Hence Department and Professor objects are weakly associated, which is nothing but Aggregation.

Coding Example:

```
1) class Student:
2)     collegeName='DURGASOFT'
3)     def __init__(self,name):
4)         self.name=name
5) print(Student.collegeName)
6) s=Student('Durga')
7) print(s.name)
```

Output:
DURGASOFT
Durga

In the above example without existing Student object there is no chance of existing his name. Hence Student Object and his name are strongly associated which is nothing but Composition.

But without existing Student object there may be a chance of existing collegeName. HenceStudent object and collegeName are weakly associated which is nothing but Aggregation.

Conclusion:
The relation between object and its instance variables is always Composition where as the relation between object and static variables is Aggregation.

Note: Whenever we are creating child class object then child class constructor will be executed. Ifthe child class does not contain constructor then parent class constructor will be executed, but parent object won't be created.

Eg:

```python
1)  class P:
2)    def __init__(self):
3)       print(id(self))
4) class C(P):
5)    pass
6) c=C()
7)  print(id(c))
```

Output:
6207088
6207088

Eg:

```python
1)  class Person:
2)    def __init__(self,name,age):
3)       self.name=name
4)       self.age=age
5)  class Student(Person):
6)    def __init__(self,name,age,rollno,marks):
7)       super().__init__(name,age)
8)       self.rollno=rollno
9)       self.marks=marks
10)   def __str__(self):
11)      return 'Name={}\nAge={}\nRollno={}\nMarks={}'.format(self.name,self.age,self.rollno
    ,self.marks)
12) s1=Student('durga',48,101,90)
13) print(s1)
```

Output:
Name=durg
aAge=48
Rollno=101
Marks=90

Note: In the above example when ever we are creating child class object both parent and childclass constructors got executed to perform initialization of child object

Types of Inheritance:

1. Single Inheritance:

The concept of inheriting the properties from one class to another class is known as singleinheritance.

Eg:

```
1)   class P:
2)     def m1(self):
3)       print("Parent Method")
4)   class C(P):
5)     def m2(self):
6)       print("Child Method")
7)   c=C()
8)   c.m1()
9)   c.m2()
```

Output:
Parent
MethodChild
Method

Single Inheritance

2. Multi Level Inheritance:

The concept of inheriting the properties from multiple classes to single class with the concept of one after another is known as multilevel inheritance

Eg:

```
1)  class P:
2)     def m1(self):
3)        print("Parent Method")
4)  class C(P):
5)     def m2(self):
6)        print("Child Method")
7)  class CC(C):
8)     def m3(self):
9)        print("Sub Child Method")
10) c=CC()
11) c.m1()
12) c.m2()
13) c.m3()
```

Output:
Parent
Method Child
Method
Sub Child Method

Multi – Level Inheritance
3. Hierarchical Inheritance:

The concept of inheriting properties from one class into multiple classes which are present atsame level is known as Hierarchical Inheritance
Hierarchical Inheritance

```
1)  class P:
2)      def m1(self):
3)          print("Parent Method")
4)  class C1(P):
5)      def m2(self):
6)          print("Child1 Method")
7)  class C2(P):
8)      def m3(self):
9)          print("Child2 Method")
10) c1=C1()
11) c1.m1()
12) c1.m2()
13) c2=C2()
14) c2.m1()
15) c2.m3()
```

Output:
**Parent
MethodChild1
MethodParent
MethodChild2
Method**

4. Multiple Inheritance:

The concept of inheriting the properties from multiple classes into a single class at a time, isknown as multiple inheritance.

Multiple Inheritance

```
1)  class P1:
2)     def m1(self):
3)        print("Parent1 Method")
4)  class P2:
5)     def m2(self):
6)        print("Parent2 Method")
7)  class C(P1,P2):
8)     def m3(self):
9)        print("Child2 Method")
10) c=C()
11) c.m1()
12) c.m2()
13) c.m3()
```

Output:
Parent1
Method Parent2
Method   Child2
Method

If the same method is inherited from both parent classes,then Python will always consider theorder of Parent classes in the declaration of the child class.

class C(P1,P2): ===>P1 method will be consideredclass C(P2,P1): ===>P2 method will be considered

Eg:

```
1)  class P1:
2)      def m1(self):
3)          print("Parent1 Method")
4)  class P2:
5)      def m1(self):
6)          print("Parent2 Method")
7)  class C(P1,P2):
8)      def m2(self):
9)          print("Child Method")
10) c=C()
11) c.m1()
12) c.m2()
```

Output:
Parent1
MethodChild
Method

5. Hybrid Inheritance:

Combination of Single, Multi level, multiple and Hierarchical inheritance is known as HybridInheritance.
6. Cyclic Inheritance:

The concept of inheriting properties from one class to another class in cyclic way, is called Cyclic inheritance.Python won't support for Cyclic Inheritance of course it is really not required.

Eg - 1:

class A(A):pass

NameError: name 'A' is not defined

Eg - 2:

```
1)  class A(B):
2)      pass
3)  class B(A):
4)      pass
```

NameError: name 'B' is not defined
Method Resolution Order (MRO):

In Hybrid Inheritance the method resolution order is decided based on MRO
algorithm.This algorithm is also known as C3 algorithm.
Samuele Pedroni proposed this
algorithm.It follows DLR (Depth First
Left to Right)
i.e Child will get more priority than Parent.
Left Parent will get more priority than Right Parent

 MRO(X)=X+Merge(MRO(P1),MRO(P2),...,ParentList)

Head Element vs Tail Terminology:

Assume C1,C2,C3,...are
classes.In the list :
C1C2C3C4C5....
C1 is considered as Head Element and remaining is considered as Tail.

How to find Merge:

Take the head of first list
If the head is not in the tail part of any other list,then add this head to the result and remove
itfrom the lists in the merge.
If the head is present in the tail part of any other list,then consider the head element of the
nextlist and continue the same process.

Note: We can find MRO of any class by using mro() function.
print(ClassName.mro())

Demo Program-1 for Method Resolution Order:
mro(A)=A,object
mro(B)=B,A,object
mro(C)=C,A,object
mro(D)=D,B,C,A,obje
ct

test.py:

```
1)  class A:pass
2)  class B(A):pass
3)  class C(A):pass
4)  class D(B,C):pass
5)  print(A.mro())
6)  print(B.mro())
7)  print(C.mro())
8)  print(D.mro())
```

Output:
[<class '__main__.A'>, <class 'object'>]
[<class '_main_.B'>, <class '_main_.A'>, <class
'object'>][<class '_main_.C'>, <class '_main_.A'>, <class
'object'>]
[<class '_main_.D'>, <class '_main_.B'>, <class '_main_.C'>, <class '_main_.A'>, <class
'object'>]

Demo Program-2 for Method Resolution Order:
mro(A)=A,object
mro(B)=B,object
mro(C)=C,object
mro(X)=X,A,B,object
mro(Y)=Y,B,C,object
mro(P)=P,X,A,Y,B,C,obje
ct

Finding mro(P) by using C3 algorithm:

Formula: MRO(X)=X+Merge(MRO(P1),MRO(P2),...,ParentList)

mro(p)= P+Merge(mro(X),mro(Y),mro(C),XYC)
    = P+Merge(XABO,YBCO,CO,XYC)
    = P+X+Merge(ABO,YBCO,CO,YC)
    = P+X+A+Merge(BO,YBCO,CO,YC)
    = P+X+A+Y+Merge(BO,BCO,CO,C)
    = P+X+A+Y+B+Merge(O,CO,CO,C)
    = P+X+A+Y+B+C+Merge(O,O,O)
    = P+X+A+Y+B+C+O

test.py:

```python
1)  class A:pass
2)  class B:pass
3)  class C:pass
4)  class X(A,B):pass
5)  class Y(B,C):pass
6)  class P(X,Y,C):pass
7)  print(A.mro())#AO
8)  print(X.mro())#XABO
9)  print(Y.mro())#YBCO
10) print(P.mro())#PXAYBCO
```

Output:
[<class '__main__.A'>, <class 'object'>]
[<class '_main_.X'>, <class '_main_.A'>, <class '_main__.B'>, <class 'object'>][<class '_main_.Y'>, <class '_main_.B'>, <class '_main_.C'>, <class 'object'>]
[<class '__main__.P'>, <class '__main__.X'>, <class '__main__.A'>, <class '__man__.Y'>, <class '_main_.B'>,
 <class '__main__.C'>, <class 'object'>]

test.py:

```python
1)  class A:
2)     def m1(self):
3)       print('A class Method')
4)  class B:
5)     def m1(self):
6)       print('B class Method')
7)  class C:
8)     def m1(self):
9)       print('C class Method')
10) class X(A,B):
11)    def m1(self):
12)      print('X class Method')
```

```
13) class Y(B,C):
14)    def m1(self):
15)       print('Y class Method')
16) class P(X,Y,C):
17)    def m1(self):
18)       print('P class Method')
19) p=P()
20) p.m1()
```

Output:
P class Method

In the above example P class m1() method will be considered.If P class does not contain m1() method then as per MRO, X class method will be considered. If X class does not contain then Aclass method will be considered and this process will be continued.

The method resolution in the following order:**PXAYBCO**

Demo Program-3 for Method Resolution Order:
mro(o)=object
mro(D)=D,object
mro(E)=E,object
mro(F)=F,object
mro(B)=B,D,E,obje
ct
mro(C)=C,D,F,obje
ct
mro(A)=A+Merge(mro(B),mro(C),BC)
   =A+Merge(BDEO,CDFO,BC)
   =A+B+Merge(DEO,CDFO,C)
   =A+B+C+Merge(DEO,DFO)
   =A+B+C+D+Merge(EO,FO)

test.py:

```
1)  class D:pass
2)  class E:pass
3)  class F:pass
4)  class B(D,E):pass
5)  class C(D,F):pass
6)  class A(B,C):pass
7)  print(D.mro())
8)  print(B.mro())
9)  print(C.mro())
10) print(A.mro())
```

Output:
[<class '__main__.D'>, <class 'object'>]
[<class '__main_.B'>, <class '_main_.D'>, <class '_main__.E'>, <class
'object'>][<class '_main_.C'>, <class '_main_.D'>, <class '_main_.F'>, <class
'object'>]
[<class '__main__.A'>, <class '__main__.B'>, <class '__main__.C'>, <class '__main__.D'>,
<class'_main_.E'>,
 <class '__main__.F'>, <class 'object'>]

super() Method:

**super() is a built-in method which is useful to call the super class constructors,variables and
methods from the child class.**

Demo Program-1 for super():

```
1)  class Person:
2)      def __init__(self,name,age):
3)          self.name=name
4)          self.age=age
5)      def display(self):
6)          print('Name:',self.name)
7)          print('Age:',self.age)
8)
9)  class Student(Person):
10)     def __init__(self,name,age,rollno,marks):
11)         super().__init__(name,age)
12)         self.rollno=rollno
13)         self.marks=marks
14)
15)     def display(self):
16)         super().display()
17)         print('Roll No:',self.rollno)
18)         print('Marks:',self.marks)
19)
20) s1=Student('Durga',22,101,90)
```

Output:
Name:
DurgaAge:
22
Roll No: 101
Marks: 90

In the above program we are using super() method to call parent class constructor and display()method

Demo Program-2 for super():

```python
1)  class P:
2)      a=10
3)      def __init__(self):
4)          self.b=10
5)      def m1(self):
6)          print('Parent instance method')
7)      @classmethod
8)      def m2(cls):
9)          print('Parent class method')
10)     @staticmethod
11)     def m3():
12)         print('Parent static method')
13)
14) class C(P):
15)     a=888
16)     def __init__(self):
17)         self.b=999
18)         super().__init__()
19)         print(super().a)
20)         super().m1()
21)         super().m2()
22)         super().m3()
23)
24) c=C()
```

Output:
10
Parent instance
methodParent class
method Parent static
method

In the above example we are using super() to call various members of Parent class.

How to call method of a particular Super class:

We can use the following approaches

1. super(D,self).m1()
It will call m1() method of super class of D.

2. A.m1(self)
It will call A class m1() method

```
1)    class A:
2)      def m1(self):
3)        print('A class Method')
4)   class B(A):
5)      def m1(self):
6)        print('B class Method')
7)   class C(B):
8)      def m1(self):
9)        print('C class Method')
10)  class D(C):
11)     def m1(self):
12)       print('D class Method')
13)  class E(D):
14)     def m1(self):
15)       A.m1(self)
16)
17)  e=E()
18)  e.m1()
```

Output:
A class Method

Various Important Points about super():

Case-1: From child class we are not allowed to access parent class instance variables by using super(),Compulsory we should use self only.
But we can access parent class static variables by using super().

Eg:

```
1)  class P:
2)      a=10
3)      def __init__(self):
4)        self.b=20
5)
6)  class C(P):
7)      def m1(self):
```

```
8)        print(super().a)#valid
9)        print(self.b)#valid
10)       print(super().b)#invalid
11) c=C()
12) c.m1()
```

Output:
10
20
AttributeError: 'super' object has no attribute 'b'

Case-2: From child class constructor and instance method, we can access parent class instancemethod,static method and class method by using super()

```
1)  class P:
2)      def __init__(self):
3)          print('Parent Constructor')
4)      def m1(self):
5)          print('Parent instance method')
6)      @classmethod
7)      def m2(cls):
8)          print('Parent class method')
9)      @staticmethod
10)     def m3():
11)         print('Parent static method')
12)
13) class C(P):
14)     def __init__(self):
15)         super().__init__()
16)         super().m1()
17)         super().m2()
18)         super().m3()
19)
20)     def m1(self):
21)         super().__init__()
22)         super().m1()
23)         super().m2()
24)         super().m3()
25)
26) c=C()
27) c.m1()
```

Output:
Parent Constructor
Parent instance
methodParent class
method Parent static
method Parent
Constructor Parent
instance method

Parent class method
Parent static
method

Case-3: From child class, class method we cannot access parent class instance methods and constructors by using super() directly(but indirectly possible). But we can access parent class staticand class methods.

```python
1)  class P:
2)      def __init__(self):
3)          print('Parent Constructor')
4)      def m1(self):
5)          print('Parent instance method')
6)      @classmethod
7)      def m2(cls):
8)          print('Parent class method')
9)      @staticmethod
10)     def m3():
11)         print('Parent static method')
12)
13) class C(P):
14)     @classmethod
15)     def m1(cls):
16)         #super().__init__()--->invalid
17)         #super().m1()--->invalid
18)         super().m2()
19)         super().m3()
20)
21) C.m1()
```

Output:
Parent class method
Parent static
method

From Class Method of Child class,how to call parent class instance methods and constructors:

```python
1)  class A:
2)      def __init__(self):
3)          print('Parent constructor')
4)
5)      def m1(self):
6)          print('Parent instance method')
7)
8)  class B(A):
9)      @classmethod
10)     def m2(cls):
11)         super(B,cls).__init__(cls)
12)         super(B,cls).m1(cls)
```

```
13)
14) B.m2()
```

Output:
Parent constructor
Parent instance
method

Case-4: In child class static method we are not allowed to use super() generally (But in special way we can use)

```
1)  class P:
2)    def __init__(self):
3)      print('Parent Constructor')
4)    def m1(self):
5)      print('Parent instance method')
6)    @classmethod
7)    def m2(cls):
8)      print('Parent class method')
9)    @staticmethod
10)   def m3():
11)     print('Parent static method')
12)
13) class C(P):
14)   @staticmethod
15)   def m1():
16)     super().m1()-->invalid
17)     super().m2()--->invalid
18)     super().m3()--->invalid
19)
20) C.m1()
```

RuntimeError: super(): no arguments

How to call parent class static method from child class static method by using super():

```
1)  class A:
2)
3)    @staticmethod
4)    def m1():
5)      print('Parent static method')
6)
7)  class B(A):
8)    @staticmethod
9)    def m2():
10)     super(B,B).m1()
11)
12) B.m2()
```

Output: Parent static method

Polymorphism

Poly means many. Morphs means forms.Polymorphism means 'Many Forms'.

Eg1: **Yourself is best example of polymorphism.In front of Your parents You will have one type ofbehaviour and with friends another type of behaviour.Same person but different behaviours at different places,which is nothing but polymorphism.**

Eg2: **+ operator acts as concatenation and arithmetic addition**

Eg3: *** operator acts as multiplication and repetition operator**

Eg4: **The Same method with different implementations in Parent class and child classes.(overriding)**

Related to polymorphism the following 4 topics are important

1. Duck Typing Philosophy of Python

2. Overloading
    1. Operator Overloading
    2. Method Overloading
    3. Constructor Overloading

3. Overriding
    1. Method overriding
    2. constructor overriding

1. Duck Typing Philosophy of Python:

In Python we cannot specify the type explicitly. Based on provided value at runtime the type willbe considered automatically. Hence Python is considered as Dynamically Typed Programming Language.

```
def
  f1(obj):
  obj.talk(
  )
```

What is the type of obj? We cannot decide at the beginning. At runtime we can pass any type.Thenhow we can decide the type?
At runtime if 'it walks like a duck and talks like a duck,it must be duck'. Python follows thisprinciple. This is called Duck Typing Philosophy of Python.

Demo Program:

```python
1)  class Duck:
2)      def talk(self):
3)          print('Quack.. Quack..')
4)
5)  class Dog:
6)      def talk(self):
7)          print('Bow Bow..')
8)
9)  class Cat:
10)     def talk(self):
11)         print('Moew Moew ..')
12)
13) class Goat:
14)     def talk(self):
15)         print('Myaah Myaah ..')
16)
17) def f1(obj):
18)     obj.talk()
19)
20) l=[Duck(),Cat(),Dog(),Goat()]
21) for obj in l:
22)     f1(obj)
```

Output:
Quack..
Quack.. Moew
Moew .. Bow
Bow..
Myaah Myaah ..

The problem in this approach is if obj does not contain talk() method then we will getAttributeError

Eg:

```python
1)  class Duck:
2)      def talk(self):
3)          print('Quack.. Quack..')
4)
5)  class Dog:
6)      def bark(self):
7)          print('Bow Bow..')
8)  def f1(obj):
9)      obj.talk()
10)
11) d=Duck()
12) f1(d)
13)
```

```
14) d=Dog()
15) f1(d)
```

Output:
D:\durga_classes>py
test.pyQuack.. Quack..
Traceback (most recent call last):
 File "test.py", line 22, in
   <module>f1(d)
 File "test.py", line 13, in
   f1obj.talk()
AttributeError: 'Dog' object has no attribute 'talk'

But we can solve this problem by using hasattr() function.

 hasattr(obj,'attributename')
 attributename can be method name or variable name

Demo Program with hasattr() function:

```
1)   class Duck:
2)     def talk(self):
3)        print('Quack.. Quack..')
4)
5)   class Human:
6)     def talk(self):
7)        print('Hello Hi...')
8)
9)   class Dog:
10)    def bark(self):
11)       print('Bow Bow..')
12)
13) def  f1(obj):
14)   if hasattr(obj,'talk'):
15)      obj.talk()
16)   elif hasattr(obj,'bark'):
17)      obj.bark()
18)
19) d=Duck()
20) f1(d)
21)
22) h=Human()
23) f1(h)
24)
25) d=Dog()
26) f1(d)
27) Myaah Myaah Myaah...
```

Overloading:

We can use same operator or methods for different purposes.

Eg1: + operator can be used for Arithmetic addition and String concatenation
    print(10+20)#30
    print('durga'+'soft')#durgasoft

Eg2: * operator can be used for multiplication and string repetition purposes.
     print(10*20)#200
     print('durga'*3)#durgadurgadurga

Eg3: We can use deposit() method to deposit cash or cheque or dd
    deposit(cash)
    deposit(cheque)
    deposit(dd)

There are 3 types of overloading
1. Operator Overloading
2. Method Overloading
3. Constructor Overloading

1. Operator Overloading:

We can use the same operator for multiple purposes, which is nothing but operator

overloading.Python supports operator overloading.

Eg1: + operator can be used for Arithmetic addition and String concatenation
    print(10+20)#30
    print('durga'+'soft')#durgasoft

Eg2: * operator can be used for multiplication and string repetition purposes.
     print(10*20)#200
     print('durga'*3)#durgadurgadurga

Demo program to use + operator for our class objects:

```
1)  class Book:
2)    def __init__(self,pages):
3)      self.pages=pages
4)
5)  b1=Book(100)
6)  b2=Book(200)
7)  print(b1+b2)
```

D:\durga_classes>py test.py
Traceback (most recent call last):
  File "test.py", line 7, in
    <module>print(b1+b2)
TypeError: unsupported operand type(s) for +: 'Book' and 'Book'

We can overload + operator to work with Book objects also. i.e Python supports OperatorOverloading.

For every operator Magic Methods are available. To overload any operator we have to overridethat Method in our class.
Internally + operator is implemented by using __add_() method.This method is called magic method for + operator. We have to override this method in our class.

Demo program to overload + operator for our Book class objects:

```
1)  class Book:
2)      def __init__(self,pages):
3)          self.pages=pages
4)
5)      def __add__(self,other):
6)          return self.pages+other.pages
7)
8)  b1=Book(100)
9)  b2=Book(200)
10) print('The Total Number of Pages:',b1+b2)
```

Output: The Total Number of Pages: 300

The following is the list of operators and corresponding magic methods.

```
+   ---> object.__add__(self,other)
-   ---> object.__sub__(self,other)
*   ---> object.__mul__(self,other)
/   ---> object.__div__(self,other)
//  ---> object.__floordiv__(self,other)
%   ---> object.__mod__(self,other)
**  ---> object.__pow__(self,other)
+=  ---> object.__iadd__(self,other)
-=  ---> object.__isub__(self,other)
*=  ---> object.__imul__(self,other)
/=  ---> object.__idiv__(self,other)
//= ---> object.__ifloordiv__(self,other)
%=  ---> object.__imod__(self,other)
**= ---> object.__ipow__(self,other)
<   ---> object.__lt__(self,other)
<=  ---> object.__le__(self,other)
>   ---> object.__gt__(self,other)
>=  ---> object.__ge__(self,other)
```

== ---> object.__eq__(self,other)

!= ---> object.__ne__(self,other)

Overloading > and <= operators for Student class objects:

```python
1)  class Student:
2)    def __init__(self,name,marks):
3)        self.name=name
4)        self.marks=marks
5)    def __gt__(self,other):
6)        return self.marks>other.marks
7)    def __le__(self,other):
8)        return self.marks<=other.marks
9)
10)
11) print("10>20 =",10>20)
12) s1=Student("Durga",100)
13) s2=Student("Ravi",200)
14) print("s1>s2=",s1>s2)
15) print("s1<s2=",s1<s2)
16) print("s1<=s2=",s1<=s2)
17) print("s1>=s2=",s1>=s2)
```

Output:
10>20 =
Falses1>s2=
False s1<s2=
True
s1<=s2=
True
s1>=s2=
False

Program to overload multiplication operator to work on Employee objects:

```python
1)  class Employee:
2)    def __init__(self,name,salary):
3)        self.name=name
4)        self.salary=salary
5)    def __mul__(self,other):
6)        return self.salary*other.days
7)
8)  class TimeSheet:
9)    def __init__(self,name,days):
10)        self.name=name
11)        self.days=days
12)
13) e=Employee('Durga',500)
14) t=TimeSheet('Durga',25)
15) print('This Month Salary:',e*t)
```

Output: This Month Salary: 12500

2. Method Overloading:

If 2 methods having same name but different type of arguments then those methods are said tobe overloaded methods.

Eg: m1(int a)
   m1(double d)

But in Python Method overloading is not possible.
If we are trying to declare multiple methods with same name and different number of argumentsthen Python will always consider only last method.

Demo Program:

```
1)  class Test:
2)     def m1(self):
3)        print('no-arg method')
4)     def m1(self,a):
5)        print('one-arg method')
6)     def m1(self,a,b):
7)        print('two-arg method')
8)
9)  t=Test()
10) #t.m1()
11) #t.m1(10)
12) t.m1(10,20)
```

Output: two-arg method

In the above program python will consider only last method.

How we can handle overloaded method requirements in Python:

Most of the times, if method with variable number of arguments required then we can handle with default arguments or with variable number of argument methods.

Demo Program with Default Arguments:

```
1)  class Test:
2)     def sum(self,a=None,b=None,c=None):
3)        if a!=None and b!= None and c!= None:
4)           print('The Sum of 3 Numbers:',a+b+c)
5)        elif a!=None and b!= None:
6)           print('The Sum of 2 Numbers:',a+b)
7)        else:
8)           print('Please provide 2 or 3 arguments')
9)
10) t=Test()
```

```
11) t.sum(10,20)
12) t.sum(10,20,30)
13) t.sum(10)
```

Output:
The Sum of 2 Numbers: 30
The Sum of 3 Numbers: 60
Please provide 2 or 3 arguments

Demo Program with Variable Number of Arguments:

```python
1) class Test:
2)   def sum(self,*a):
3)     total=0
4)     for x in a:
5)       total=total+x
6)     print('The Sum:',total)
7)
8)
9) t=Test()
10) t.sum(10,20)
11) t.sum(10,20,30)
12) t.sum(10)
13) t.sum()
```

3. Constructor Overloading:

Constructor overloading is not possible in Python.
If we define multiple constructors then the last constructor will be considered.

```python
1)  class Test:
2)    def __init__(self):
3)      print('No-Arg Constructor')
4)
5)    def __init__(self,a):
6)      print('One-Arg constructor')
7)
8)    def __init__(self,a,b):
9)      print('Two-Arg constructor')
10) #t1=Test()
11) #t1=Test(10)
12) t1=Test(10,20)
```

Output: **Two-Arg constructor**

In the above program only Two-Arg Constructor is available.

But based on our requirement we can declare constructor with default arguments and variablenumber of arguments.

Constructor with Default Arguments:

```python
1)  class Test:
2)     def __init__(self,a=None,b=None,c=None):
3)        print('Constructor with 0|1|2|3 number of arguments')
4)
5)  t1=Test()
6)  t2=Test(10)
7)  t3=Test(10,20)
8)  t4=Test(10,20,30)
```

Output:
Constructor with 0|1|2|3 number of arguments
Constructor with 0|1|2|3 number of arguments
Constructor with 0|1|2|3 number of arguments
Constructor with 0|1|2|3 number of arguments

Constructor with Variable Number of Arguments:

```python
1)  class Test:
2)     def __init__(self,*a):
3)        print('Constructor with variable number of arguments')
4)
5)  t1=Test()
6)  t2=Test(10)
7)  t3=Test(10,20)
8)  t4=Test(10,20,30)
9)  t5=Test(10,20,30,40,50,60)
```

Output:
Constructor with variable number of arguments Constructor with variable number of arguments Constructor with variable number of arguments Constructor with variable number of arguments Constructor with variable number of arguments

Method overriding:

What ever members available in the parent class are bydefault available to the child class throughinheritance. If the child class not satisfied with parent class implementation then child class is allowed to redefine that method in the child class based on its requirement. This concept is calledoverriding.
Overriding concept applicable for both methods and constructors.

Demo Program for Method overriding:

```python
1) class P:
2)     def property(self):
3)         print('Gold+Land+Cash+Power')
4)     def marry(self):
5)         print('Appalamma')
6) class C(P):
7)     def marry(self):
8)         print('Katrina Kaif')
9)
10) c=C()
11) c.property()
12) c.marry()
```

Output:
Gold+Land+Cash+Power
Katrina Kaif

From Overriding method of child class,we can call parent class method also by using super() method.

```python
1) class P:
2)     def property(self):
3)         print('Gold+Land+Cash+Power')
4)     def marry(self):
5)         print('Appalamma')
6) class C(P):
7)     def marry(self):
8)         super().marry()
9)         print('Katrina Kaif')
10)
11) c=C()
12) c.property()
13) c.marry()
```

Output:
Gold+Land+Cash+Power
Appalamma
Katrina Kaif

Demo Program for Constructor overriding:

```python
1) class P:
2)    def __init__(self):
3)       print('Parent Constructor')
4)
5) class C(P):
6)    def __init__(self):
7)       print('Child Constructor')
8)
9) c=C()
```

Output: Child Constructor

In the above example,if child class does not contain constructor then parent class constructor willbe executed

From child class constuctor we can call parent class constructor by using super() method.

Demo Program to call Parent class constructor by using super():

```python
1)  class Person:
2)     def __init__(self,name,age):
3)        self.name=name
4)        self.age=age
5)
6)  class Employee(Person):
7)     def __init__(self,name,age,eno,esal):
8)        super().__init__(name,age)
9)        self.eno=eno
10)       self.esal=esal
11)
12)    def display(self):
13)       print('Employee Name:',self.name)
14)       print('Employee Age:',self.age)
15)       print('Employee Number:',self.eno)
16)       print('Employee Salary:',self.esal)
17)
18) e1=Employee('Durga',48,872425,26000)
19) e1.display()
20) e2=Employee('Sunny',39,872426,36000)
21) e2.display()
```

Output:
Employee Name:
DurgaEmployee Age:
48
Employee Number: 872425
Employee   Salary:
26000Employee Name:
Sunny Employee Age:
39

Employee Number: 872426
Employee Salary: 36000

OOPs Part - 4

1. Abstract Method
2. Abstract class
3. Interface
4. Public,Private and Protected Members
5. __str__() method
6. Difference between str() and repr() functions
7. Small Banking Application

Abstract Method:

Sometimes we don't know about implementation,still we can declare a method. Such type ofmethods are called abstract methods.i.e abstract method has only declaration but not implementation.
In python we can declare abstract method by using @abstractmethod decorator as follows.

@abstractmethod
def m1(self): pass

@abstractmethod decorator present in abc module. Hence compulsory we should import abcmodule,otherwise we will get error.
abc==>abstract base class module

```
1) class Test:
2)     @abstractmethod
3)     def m1(self):
4)         pass
```

NameError: name 'abstractmethod' is not

definedEg:

```
1) from abc import *
2) class Test:
3)     @abstractmethod
4)     def m1(self):
5)         pass
```

Eg:

```
1)  from abc import *
2) class Fruit:
3)     @abstractmethod
4)     def taste(self):
5)         pass
```

Child classes are responsible to provide implemention for parent class abstract methods.

Abstract class:

Some times implementation of a class is not complete,such type of partially implementation classes are called abstract classes. Every abstract class in Python should be derived from ABC classwhich is present in abc module.

Case-1:

```
1)  from abc import *
2) class Test:
3)     pass
4)
5) t=Test()
```

In the above code we can create object for Test class b'z it is concrete class and it does not conatinany abstract method.

Case-2:

```
1)  from abc import *
2) class Test(ABC):
3)     pass
4)
5) t=Test()
```

In the above code we can create object,even it is derived from ABC class,b'z it does not containany abstract method.

Case-3:

```
1)  from abc import *
2) class Test(ABC):
3)     @abstractmethod
4)     def m1(self):
5)         pass
6)
7)  t=Test()
```

TypeError: Can't instantiate abstract class Test with abstract methods

m1Case-4:

```
1)  from abc import *
2)  class Test:
3)      @abstractmethod
4)      def m1(self):
5)          pass
6)
7)  t=Test()
```

We can create object even class contains abstract method b'z we are not extending ABC

class.Case-5:

```
1)  from abc import *
2)  class Test:
3)      @abstractmethod
4)      def m1(self):
5)          print('Hello')
6)
7)  t=Test()
8)  t.m1()
```

<u>Output:</u> Hello

Conclusion: If a class contains atleast one abstract method and if we are extending ABC class theninstantiation is not possible.

"abstract class with abstract method instantiation is not possible"

Parent class abstract methods should be implemented in the child classes. otherwise we cannot instantiate child class.If we are not creating child class object then we won't get any error.

Case-1:

```
1)  from abc import *
2)  class Vehicle(ABC):
3)      @abstractmethod
4)      def noofwheels(self):
5)          pass
6)
7)  class Bus(Vehicle): pass
```

It is valid b'z we are not creating Child class object

Case-2:

```
1) from abc import *
2) class Vehicle(ABC):
3)    @abstractmethod
4)    def noofwheels(self):
5)       pass
6)
7) class Bus(Vehicle): pass
8) b=Bus()
```

TypeError: Can't instantiate abstract class Bus with abstract methods noofwheels

Note: **If we are extending abstract class and does not override its abstract method then child classis also abstract and instantiation is not possible.**

Eg:

```
1) from abc import *
2) class Vehicle(ABC):
3)    @abstractmethod
4)    def noofwheels(self):
5)       pass
6)
7) class Bus(Vehicle):
8)    def noofwheels(self):
9)       return 7
10)
11) class Auto(Vehicle):
12)    def noofwheels(self):
13)       return 3
14) b=Bus()
15) print(b.noofwheels())#7
16)
17) a=Auto()
18) print(a.noofwheels())#3
```

Note: **Abstract class can contain both abstract and non-abstract methods also.**

Interfaces In Python:

In general if an abstract class contains only abstract methods such type of abstract class isconsidered as interface.

Demo program:

```
1)  from abc import *
2)  class DBInterface(ABC):
3)      @abstractmethod
4)      def connect(self):pass
5)
6)      @abstractmethod
7)      def disconnect(self):pass
8)
9)  class Oracle(DBInterface):
10)     def connect(self):
11)         print('Connecting to Oracle Database...')
12)     def disconnect(self):
13)         print('Disconnecting to Oracle Database...')
14)
15) class Sybase(DBInterface):
16)     def connect(self):
17)         print('Connecting to Sybase Database...')
18)     def disconnect(self):
19)         print('Disconnecting to Sybase Database...')
20)
21) dbname=input('Enter Database Name:')
22) classname=globals()[dbname]
23) x=classname()
24) x.connect()
25) x.disconnect()
```

D:\durga_classes>py test.py
Enter Database Name:Oracle
Connecting to Oracle
Database...
Disconnecting to Oracle Database...

D:\durga_classes>py test.py
Enter Database Name:Sybase
Connecting to Sybase
Database...
Disconnecting to Sybase Database...

Note: The inbuilt function globals()[str] converts the string 'str' into a class name and returns the classname.

Demo Program-2: Reading class name from the file

config.txt:
EPSON

test.py:

```python
1)  from abc import *
2)  class Printer(ABC):
3)      @abstractmethod
4)      def printit(self,text):pass
5)
6)      @abstractmethod
7)      def disconnect(self):pass
8)
9)  class EPSON(Printer):
10)     def printit(self,text):
11)         print('Printing from EPSON Printer...')
12)         print(text)
13)     def disconnect(self):
14)         print('Printing completed on EPSON Printer...')
15)
16) class HP(Printer):
17)     def printit(self,text):
18)         print('Printing from HP Printer...')
19)         print(text)
20)     def disconnect(self):
21)         print('Printing completed on HP Printer...')
22)
23) with open('config.txt','r') as f:
24)     pname=f.readline()
25)
26) classname=globals()[pname]
27) x=classname()
28) x.printit('This data has to print...')
29) x.disconnect()
```

Output:
Printing from EPSON
Printer...This data has to
print...
Printing completed on EPSON Printer...

Concreate class vs Abstract Class vs Inteface:

1. If we dont know anything about implementation just we have requirement specification thenwe should go for interface.

2. If we are talking about implementation but not completely then we should go for abstractclass.(partially implemented class)

3. If we are talking about implementation completely and ready to provide service then we shouldgo for concrete class.

```python
1)  from abc import *
2)  class CollegeAutomation(ABC):
3)      @abstractmethod
4)      def m1(self): pass
5)      @abstractmethod
6)      def m2(self): pass
7)      @abstractmethod
8)      def m3(self): pass
9)  class AbsCls(CollegeAutomation):
10)     def m1(self):
11)         print('m1 method implementation')
12)     def m2(self):
13)         print('m2 method implementation')
14)
15) class ConcreteCls(AbsCls):
16)     def m3(self):
17)         print('m3 method implemnentation')
18)
19) c=ConcreteCls()
20) c.m1()
21) c.m2()
22) c.m3()
```

Public, Protected and Private Attributes:

By default every attribute is public. We can access from anywhere either within the class or fromoutside of the class.

Eg:
name='durga'

Protected attributes can be accessed within the class anywhere but from outside of the class onlyin child classes. We can specify an attribute as protected by prefexing with _ symbol.

syntax:
_variablename=value

Eg:

_name='durga'

But is is just convention and in reality does not exists protected attributes.

private attributes can be accessed only within the class.i.e from outside of the class we cannotaccess. We can declare a variable as private explicitly by prefexing with 2 underscore symbols.

syntax:

variablename=valueEg:

name='durga'

Demo Program:

```
1)  class Test:
2)      x=10
3)      _y=20
4)      __z=30
5)      def m1(self):
6)          print(Test.x)
7)          print(Test._y)
8)          print(Test.__z)
9)
10) t=Test()
11) t.m1()
12) print(Test.x)
13) print(Test._y)
14) print(Test.__z)
```

Output:
```
10
20
30
10
20
Traceback (most recent call last):
 File "test.py", line 14, in
   <module>print(Test.__z)
AttributeError: type object 'Test' has no attribute '__z'
```

How to access private variables from outside of the class:

We cannot access private variables directly from outside of the class.
But we can access indirectly as follows

objectreference._classname_variablename

Eg:

```python
1) class Test:
2)    def __init__(self):
3)       self.__x=10
4)
5) t=Test()
6) print(t._Test__x)#10
```

__str__() method:

Whenever we are printing any object reference internally __str_() method will be called which is returns string in the following format

<__main__.classname object at 0x022144B0>

To return meaningful string representation we have to override __str_() method.

Demo Program:

```python
1)  class Student:
2)     def __init__(self,name,rollno):
3)        self.name=name
4)        self.rollno=rollno
5)
6)     def __str__(self):
7)        return 'This is Student with Name:{} and Rollno:{}'.format(self.name,self.rollno)
8)
9)  s1=Student('Durga',101)
10) s2=Student('Ravi',102)
11) print(s1)
12) print(s2)
```

output without overriding __str__():

<__main__.Student object at 0x022144B0>
<__main__.Student object at 0x022144D0>

output with overriding __str__():

This is Student with Name:Durga and
Rollno:101This is Student with Name:Ravi and
Rollno:102

Difference between str() and repr() OR Difference between __str__() and __repr

()str() internally calls __str_() function and hence functionality of both is same

Similarly,repr() internally calls __repr_() function and hence functionality of both is

same.

str() returns a string containing a nicely printable representation object.
The main purpose of str() is for readability.It may not possible to convert result string to original
object.

Eg:

```
1)  import datetime
2)  today=datetime.datetime.now()
3)  s=str(today)#converting datetime object to str
4)  print(s)
5)  d=eval(s)#converting str object to datetime
```

D:\durgaclasses>py test.py
2018-05-18 22:48:19.890888
Traceback (most recent call last):
  File "test.py", line 5, in <module>
  d=eval(s)#converting str object to datetime
  File "<string>", line 1
    2018-05-18 22:48:19.890888
        ^
SyntaxError: invalid token

But repr() returns a string containing a printable representation of object.
The main goal of repr() is unambigouous. We can convert result string to original object by
usingeval() function,which may not possible in str() function.

Eg:

```
1)  import datetime
2)  today=datetime.datetime.now()
3)  s=repr(today)#converting datetime object to str
4)  print(s)
5)  d=eval(s)#converting str object to datetime
6)  print(d)
```

Output:
datetime.datetime(2018, 5, 18, 22, 51, 10, 875838)
2018-05-18 22:51:10.875838

Note: It is recommended to use repr() instead of str()

Mini Project: Banking Application

```python
1)  class Account:
2)      def __init__(self,name,balance,min_balance):
3)          self.name=name
4)          self.balance=balance
5)          self.min_balance=min_balanc
e6)
7)      def deposit(self,amount):
8)          self.balance
+=amount9)
10)     def withdraw(self,amount):
11)         if self.balance-amount >= self.min_balance:
12)             self.balance -=amount
13)         else:
14)             print("Sorry, Insufficient
Funds")15)
16)     def printStatement(self):
17)         print("Account
Balance:",self.balance)18)
19) class Current(Account):
20)     def __init__(self,name,balance):
21)         super().__init__(name,balance,min_balance=-1000)
22)     def __str__(self):
23)         return "{}'s Current Account with Balance
:{}".format(self.name,self.balance)24)
25) class Savings(Account):
26)     def __init__(self,name,balance):
27)         super().__init__(name,balance,min_balance=0)
28)     def __str__(self):
29)         return "{}'s Savings Account with Balance
:{}".format(self.name,self.balance)30)
31) c=Savings("Durga",10000)
32) print(c)
33) c.deposit(5000)
34) c.printStatement()
35) c.withdraw(16000)
36) c.withdraw(15000)
37) print(c
)38)
39) c2=Current('Ravi',20000)
40) c2.deposit(6000)
41) print(c2)
42) c2.withdraw(27000)
43) print(c2)
```

Output:

D:\durgaclasses>py test.py

Durga's Savings Account with Balance :10000Account Balance: 15000

Sorry, Insufficient Funds

Durga's Savings Account with Balance :0

Ravi's Current Account with Balance :26000Ravi's Current Account with Balance :-1000

Regular Expressions

If we want to represent a group of Strings according to a particular format/pattern then we should go for Regular Expressions.

i.e Regualr Expressions is a declarative mechanism to represent a group of Strings accroding toparticular format/pattern.

Eg 1: We can write a regular expression to represent all mobile numbers
Eg 2: We can write a regular expression to represent all mail ids.

The main important application areas of Regular Expressions are

1. To develop validation frameworks/validation logic
2. To develop Pattern matching applications (ctrl-f in windows, grep in UNIX etc)
3. To develop Translators like compilers, interpreters etc
4. To develop digital circuits
5. To develop communication protocols like TCP/IP, UDP etc.

We can develop Regular Expression Based applications by using python module: re
This module contains several inbuilt functions to use Regular Expressions very easily in ourapplications.

1. compile()

re module contains compile() function to compile a pattern into RegexObject.

`pattern = re.compile("ab")`

2. finditer():

Returns an Iterator object which yields Match object for every Match

`matcher = pattern.finditer("abaababa")`

On Match object we can call the following methods.

1. start() ☐ Returns start index of the match
2. end() ☐ Returns end+1 index of the match
3. group() ☐ Returns the matched string

Eg:

```
1)  import re  count=0
2)  pattern=re.compile("ab")
3)  matcher=pattern.finditer("abaababa")
4)  for match in matcher:
5)      count+=1
6)      print(match.start(),"...",match.end(),"...",match.group())
7)  print("The number of occurrences: ",count)
```

Output:
0 ... 2 ... ab
3 ... 5 ... ab
5 ... 7 ... ab
The number of occurrences: 3

Note: **We can pass pattern directly as argument to finditer() function.**

Eg:

```
1)   import re
2)  count=0
3)  matcher=re.finditer("ab","abaababa")
4)  for match in matcher:
5)      count+=1
6)      print(match.start(),"...",match.end(),"...",match.group())
7)  print("The number of occurrences: ",count)
```

Output:

0 ... 2 ... ab
3 ... 5 ... ab
5 ... 7 ... ab
The number of occurrences: 3

Character classes:

We can use character classes to search a group of characters

1. [abc]===>Either a or b or c
2. [^abc] ===>Except a and b and c
3. [a-z]==>Any Lower case alphabet symbol
4. [A-Z]===>Any upper case alphabet symbol
5. [a-zA-Z]==>Any alphabet symbol
6. [0-9] Any digit from 0 to 9
7. [a-zA-Z0-9]==>Any alphanumeric character
8. [^a-zA-Z0-9]==>Except alphanumeric characters(Special Characters)

Eg:

```
1) import re
2) matcher=re.finditer("x","a7b@k9z")
3) for match in matcher:
4)     print(match.start()," ....",match.group())
```

<u>x = [abc]</u>
0 ....a
2 ....b

<u>x = [^abc]</u>
1 7
3 ...... @
4 ....k
5 9
6 ....z

<u>x = [a-z]</u>
0 ....a
2 ....b
4 ....k
6 ....z

<u>x = [0-9]</u>
1 7
5 9

<u>x = [a-zA-Z0-9]</u>
0 ....a
1 7
2 ....b
4 ....k
5 9
6 ....z

<u>x = [^a-zA-Z0-9]</u>
3 ...... @

Pre defined Character classes:

\s □ Space character
\S □ Any character except space character
\d □ Any digit from 0 to 9
\D □ Any character except digit
\w □ Any word character [a-zA-Z0-9]
\W □ Any character except word character (Special Characters)
. □ Any character including special characters

Eg:

```
1) import re
2) matcher=re.finditer("x","a7b k@9z")
3) for match in matcher:
4)     print(match.start()," ....",match.group())
```

x = \s:
3 ......

x = \S:
0 ....a
1 7
2 ....b
4 ....k
5 ...... @
6 9
7 ....z

x = \d:
1 7
6 9

x = \D:
0 ....a
2 ....b
3 ......
4 ....k
5 ...... @
7 ....z

x = \w:
0 ....a
1 7
2 ....b
4 ....k
6 9
7 ....z

x = \W:
3 ......
5 ...... @

x = .
0 ....a
1 7
2 ....b
3 ......

4 ....k
5 ...... @
6 9
7 ....z

Qunatifiers:

We can use quantifiers to specify the number of occurrences to match.

a □ Exactly one 'a'
a+ □ Atleast one 'a'
a* □ Any number of a's including zero number
a? □ Atmost one 'a' ie either zero number or one number
a{m} □ Exactly m number of a's
a{m,n} □ Minimum m number of a's and Maximum n number of a's

Eg:

```
1) import re
2) matcher=re.finditer("x","abaabaaab")
3) for match in matcher:
4)     print(match.start()," ....",match.group())
```

x = a:
0 ....a
2 ....a
3 ....a
5 ....a
6 ....a
7 ....a

x = a+:
0 ....a
2 ....aa
5 ....aaa

x = a*:
0 ....a
1 ......
2 ....aa
4 ......
5 ....aaa
8 ......
9 ......

x = a?:
0 ....a
1 ......
2 ....a
3 ....a
4 ......
5 ....a
6 ....a
7 ....a
8 ......
9 ......

x = a{3}:
5 ....aaa

x = a{2,4}:
2 ....aa
5 ....aaa

Note:
^x ☐ It will check whether target string starts with x or notx$ ☐ It will check whether target string ends with x or not

Important functions of re module:

1. match()
2. fullmatch()
3. search()
4.findall()
5.finditer(
)
6. sub()
7.subn()
8. split()
9. compile()

1. match():

We can use match function to check the given pattern at beginning of target string.If the match is available then we will get Match object, otherwise we will get None.

Eg:

```
1)  import re
2)  s=input("Enter pattern to check: ")
3)  m=re.match(s,"abcabdefg")
4)  if m!= None:
5)      print("Match is available at the beginning of the String")
6)      print("Start Index:",m.start(), "and End Index:",m.end())
```

```
7)  else:
8)      print("Match is not available at the beginning of the String")
```

Output:

D:\python_classes>py test.py
Enter pattern to check: abc
Match is available at the beginning of the
StringStart Index: 0 and End Index: 3

D:\python_classes>py test.py
Enter pattern to check: bde
Match is not available at the beginning of the String

2. fullmatch():

We can use fullmatch() function to match a pattern to all of target string. i.e complete string should be matched according to given pattern.
If complete string matched then this function returns Match object otherwise it returns None.

Eg:

```
1)  import re
2)  s=input("Enter pattern to check: ")
3)  m=re.fullmatch(s,"ababab")
4)  if m!= None:
5)      print("Full String Matched")
6)  else:
7)      print("Full String not Matched")
```

Output:

D:\python_classes>py
test.pyEnter pattern to
check: ab Full String not
Matched

D:\python_classes>py test.py
Enter pattern to check:
abababFull String Matched

3. search():

We can use search() function to search the given pattern in the target string.
If the match is available then it returns the Match object which represents first occurrence of thematch.
If the match is not available then it returns None

Eg:

```
1) import re
2) s=input("Enter pattern to check: ")
3) m=re.search(s,"abaaaba")
4) if m!= None:
5)     print("Match is available")
6)     print("First Occurrence of match with start index:",m.start(),"and end
index:",m.end())
7) else:
8)     print("Match is not available")
```

Output:

D:\python_classes>py test.py
Enter pattern to check: aaa
Match is available
First Occurrence of match with start index: 2 and end index: 5

D:\python_classes>py test.py
Enter pattern to check: bbb
Match is not available

4. findall():

To find all occurrences of the match.
This function returns a list object which contains all occurrences.

Eg:

```
1) import re
2) l=re.findall("[0-9]","a7b9c5kz")
3) print(l)
```

Output: ['7', '9', '5']

5. finditer():

Returns the iterator yielding a match object for each match.
On each match object we can call start(), end() and group() functions.

Eg:

```
1) import re
2) itr=re.finditer("[a-z]","a7b9c5k8z")
3) for m in itr:
4)     rint(m.start(),"...",m.end(),"...",m.group())
```

Output:
D:\python_classes>py test.py
0 ... 1 ... a
2 ... 3 ... b
4 ... 5 ... c
6 ... 7 ... k
8 ... 9 ... z

6. sub():

sub means substitution or replacement

re.sub(regex,replacement,targetstring)
In the target string every matched pattern will be replaced with provided replacement.

Eg:

```
1)  import re
2) s=re.sub("[a-z]","#","a7b9c5k8z")
3)  print(s)
```

Output: #7#9#5#8#

Every alphabet symbol is replaced with # symbol

7. subn():

It is exactly same as sub except it can also returns the number of replacements.
This function returns a tuple where first element is result string and second element is number ofreplacements.
        (resultstring, number of replacements)

Eg:

```
1)  import re
2) t=re.subn("[a-z]","#","a7b9c5k8z")
3)  print(t)
4) print("The Result String:",t[0])
5)  print("The number of replacements:",t[1])
```

Output:
D:\python_classes>py test.py
('#7#9#5#8#', 5)
The Result String: #7#9#5#8#
The number of replacements:
5

8. split():

If we want to split the given target string according to a particular pattern then we should go forsplit() function.
This function returns list of all tokens.

Eg:

```
1)  import re
2)  l=re.split(",","sunny,bunny,chinny,vinny,pinny")
3)  print(l)
4)  for t in l:
5)      print(t)
```

Output:
D:\python_classes>py test.py
['sunny', 'bunny', 'chinny', 'vinny',
'pinny']sunny
bunny
chinn
y
vinny
pinny

Eg:

```
1)  import re
2)  l=re.split("\.","www.durgasoft.com")
3)  for t in l:
4)      print(t)
```

Output:
D:\python_classes>py test.py
www
durgasof
tcom

^ symbol:

We can use ^ symbol to check whether the given target string starts with our provided pattern ornot.

Eg:
res=re.search("^Learn",s)
if the target string starts with Learn then it will return Match object,otherwise returns None.

test.py:

```python
1) import re
2) s="Learning Python is Very Easy"
3) res=re.search("^Learn",s)
4) if res != None:
5)     print("Target String starts with Learn")
6) else:
7)     print("Target String Not starts with Learn")
```

Output: Target String starts with Learn

$ symbol:

We can use $ symbol to check whether the given target string ends with our provided pattern ornot

Eg: res=re.search("Easy$",s)

If the target string ends with Easy then it will return Match object,otherwise returns None.

test.py:

```python
1) import re
2) s="Learning Python is Very Easy"
3) res=re.search("Easy$",s)
4) if res != None:
5)     print("Target String ends with Easy")
6) else:
7)     print("Target String Not ends with Easy")
```

Output: Target String ends with Easy

Note: If we want to ignore case then we have to pass 3rd argument re.IGNORECASE for search()function.

Eg: res = re.search("easy$",s,re.IGNORECASE)

test.py:

```python
1) import re
2) s="Learning Python is Very Easy"
3) res=re.search("easy$",s,re.IGNORECASE)
4) if res != None:
5)     print("Target String ends with Easy by ignoring case")
6) else:
7)     print("Target String Not ends with Easy by ignoring case")
```

App1: Write a Regular Expression to represent all Yava language identifiers

Rules:

1. The allowed characters are   a-z,A-Z,0-9,#
2. The first character should be a lower case alphabet symbol from a to k
3. The second character should be a digit divisible by 3
4. The length of identifier should be atleast

2.[a-k][0369][a-zA-Z0-9#]*

App2: Write a python program to check whether the given string is Yavalanguage identifier or not?

```
1)  import re
2) s=input("Enter Identifier:")
3)  m=re.fullmatch("[a-k][0369][a-zA-Z0-9#]*",s)
4) if m!= None:
5)     print(s,"is valid Yava Identifier")
6) else:
7)     print(s,"is invalid Yava Identifier")
```

Output:

D:\python_classes>py test.py
Enter Identifier:a6kk9z##
a6kk9z## is valid Yava
Identifier

D:\python_classes>py test.py
Enter Identifier:k9b876
k9b876 is valid Yava
Identifier

D:\python_classes>py test.py
Enter Identifier:k7b9
k7b9 is invalid Yava Identifier

App3: Write a Regular Expression to represent all 10 digit mobile numbers.

Rules:

1. Every number should contains exactly 10 digits
2. The first digit should be 7 or 8 or 9

[7-9][0-9][0-9][0-9][0-9][0-9][0-9][0-9][0-9][0-9]
   or

[7-9][0-9]{9}
   or
[7-9]\d{9}

App4: Write a Python Program to check whether the given number is valid mobile number or not?

```
1)  import re
2)  n=input("Enter number:")
3)  m=re.fullmatch("[7-9]\d{9}",n)
4)  if m!= None:
5)      print("Valid Mobile Number")
6)  else:
7)      print("Invalid Mobile Number")
```

Output:

D:\python_classes>py test.py
Enter number:9898989898
Valid Mobile Number

D:\python_classes>py test.py
Enter number:6786786787
Invalid Mobile Number

D:\python_classes>py test.py
Enter number:898989
Invalid Mobile Number

App5: Write a python program to extract all mobile numbers present in input.txt where numbers are mixed with normal text data

```
1)  import re
2)  f1=open("input.txt","r")
3)  f2=open("output.txt","w")
4)  for line in f1:
5)      list=re.findall("[7-9]\d{9}",line)
6)      for n in list:
7)          f2.write(n+"\n")
8)  print("Extracted all Mobile Numbers into output.txt")
9)  f1.close()
10) f2.close()
```

Web Scraping by using Regular Expressions:

The process of collecting information from web pages is called web scraping. In web scraping to match our required patterns like mail ids, mobile numbers we can use regular expressions.

Eg:

```
1)  import re,urllib
2)  import urllib.request
3)  sites="google rediff".split()
4)  print(sites)
5)  for s in sites:
6)      print("Searching...",s)
7)      u=urllib.request.urlopen("http://"+s+".com")
8)      text=u.read()
9)      title=re.findall("<title>.*</title>",str(text),re.I)
10)     print(title[0])
```

Eg: Program to get all phone numbers of redbus.in by using web scraping and regular expressions

```
1)  import re,urllib
2)  import urllib.request
3)  u=urllib.request.urlopen("https://www.redbus.in/info/contactus")
4)  text=u.read()
5)  numbers=re.findall("[0-9-]{7}[0-9-]+",str(text),re.I)
6)  for n in numbers:
7)      print(n)
```

Q. Write a Python Program to check whether the given mail id is valid gmail id or not?

```
1)  import re
2)  s=input("Enter Mail id:")
3)  m=re.fullmatch("\w[a-zA-Z0-9_.]*@gmail[.]com",s)
4)  if m!=None:
5)      print("Valid Mail Id");
6)  else:
7)      print("Invalid Mail id")
```

Output:

D:\python_classes>py test.py
Enter Mail
id:durgatoc@gmail.comValid
Mail Id

D:\python_classes>py
test.pyEnter Mail
id:durgatoc Invalid Mail id

D:\python_classes>py test.py
Enter Mail
id:durgatoc@yahoo.co.inInvalid
Mail id

Q. Write a python program to check whether given car registration number is valid Telangana State Registration number or not?

```
1)  import re
2) s=input("Enter Vehicle Registration Number:")
3)  m=re.fullmatch("TS[012][0-9][A-Z]{2}\d{4}",s)
4) if m!=None:
5)     print("Valid Vehicle Registration Number");
6) else:
7)     print("Invalid Vehicle Registration Number")
```

Output:

D:\python_classes>py test.py
Enter Vehicle Registration
Number:TS07EA7777Valid Vehicle
Registration Number

D:\python_classes>py test.py
Enter Vehicle Registration
Number:TS07KF0786Valid Vehicle
Registration Number

D:\python_classes>py test.py
Enter Vehicle Registration
Number:AP07EA7898Invalid Vehicle
Registration Number

Q. Python Program to check whether the given mobile number is valid OR not (10 digit OR 11 digit OR 12 digit)

```
1)  import re
2) s=input("Enter Mobile Number:")
3)  m=re.fullmatch("(0|91)?[7-9][0-9]{9}",s)
4) if m!=None:
5)     print("Valid Mobile Number");
6) else:
7)     print("Invalid Mobile Number")
```

Summary table and some more examples.

Multi Threading

Multi Tasking:

Executing several tasks simultaneously is the concept of multitasking.

There are 2 types of Multi Tasking
  1. Process based Multi Tasking
  2. Thread based Multi Tasking

1. Process based Multi Tasking:

Executing several tasks simmultaneously where each task is a seperate independent process iscalled process based multi tasking.

Eg: while typing python program in the editor we can listen mp3 audio songs from the same system. At the same time we can download a file from the internet. All these taks are executing simultaneously and independent of each other. Hence it is process based multi tasking.

This type of multi tasking is best suitable at operating system level.

2. Thread based MultiTasking:

Executing several tasks simultaneously where each task is a seperate independent part of the same program, is called Thread based multi tasking, and each independent part is called a Thread.

This type of multi tasking is best suitable at programmatic level.

Note: Whether it is process based or thread based, the main advantage of multi tasking is to improve performance of the system by reducing response time.

The main important application areas of multi threading are:
1. To implement Multimedia graphics
2. To develop animations
3. To develop video games
4. To develop web and application
serversetc...

Note: Where ever a group of independent jobs are available, then it is highly recommended to execute simultaneously instead of executing one by one.For such type of cases we should go forMulti Threading.

Python provides one inbuilt module "threading" to provide support for developing threads. Hencedeveloping multi threaded Programs is very easy in python.

Every Python Program by default contains one thread which is nothing but MainThread.

Q.Program to print name of current executing thread:

```
1) import threading
2) print("Current Executing Thread:",threading.current_thread().getName())
```

o/p: Current Executing Thread: MainThread

Note: threading module contains function current_thread() which returns the current executingThread object. On this object if we call getName() method then we will get current executing thread name.

The ways of Creating Thread in Python:

We can create a thread in Python by using 3 ways
1. Creating a Thread without using any class
2. Creating a Thread by extending Thread class
3. Creating a Thread without extending Thread class

1. Creating a Thread without using any class:

```
1) from threading import *
2) def display():
3)     for i in range(1,11):
4)         print("Child Thread")
5) t=Thread(target=display) #creating Thread object
6) t.start() #starting of Thread
7) for i in range(1,11):
8)     print("Main Thread")
```

If multiple threads present in our program, then we cannot expect execution order and hence wecannot expect exact output for the multi threaded programs. B'z of this we cannot provide exact output for the above program.It is varied from machine to machine and run to run.

Note: Thread is a pre defined class present in threading module which can be used to create ourown Threads.

2. Creating a Thread by extending Thread class

We have to create child class for Thread class. In that child class we have to override run() methodwith our required job. Whenever we call start() method then automatically run() method will be executed and performs our job.

```
1) from threading import *
2) class MyThread(Thread):
```

```
3)      def run(self):
4)         for i in range(10):
5)            print("Child Thread-1")
6) t=MyThread()
7) t.start()
8) for i in range(10):
9)    print("Main Thread-1")
```

3. Creating a Thread without extending Thread class:

```
1) from threading import *
2) class Test:
3)    def display(self):
4)       for i in range(10):
5)          print("Child Thread-2")
6) obj=Test()
7) t=Thread(target=obj.display)
8) t.start()
9) for i in range(10):
10)   print("Main Thread-2")
```

Without multi threading:

```
1)  from threading import *
2) import time
3) def doubles(numbers):
4)    for n in numbers:
5)       time.sleep(1)
6)       print("Double:",2*n)
7)  def squares(numbers):
8)    for n in numbers:
9)       time.sleep(1)
10)       print("Square:",n*n)
11) numbers=[1,2,3,4,5,6]
12) begintime=time.time()
13) doubles(numbers)
14) squares(numbers)
15) print("The total time taken:",time.time()-begintime)
```

With multithreading:

```
1) from threading import *
2) import time
3) def doubles(numbers):
4)    for n in numbers:
5)       time.sleep(1)
6)       print("Double:",2*n)
7) def squares(numbers):
8)    for n in numbers:
```

```
9)        time.sleep(1)
10)       print("Square:",n*n)
11)
12) numbers=[1,2,3,4,5,6]
13) begintime=time.time()
14) t1=Thread(target=doubles,args=(numbers,))
15) t2=Thread(target=squares,args=(numbers,))
16) t1.start()
17) t2.start()
18) t1.join()
19) t2.join()
20) print("The total time taken:",time.time()-begintime)
```

Setting and Getting Name of a Thread:

Every thread in python has name. It may be default name generated by Python or CustomizedName provided by programmer.

We can get and set name of thread by using the following Thread class

methods.t.getName() ☐ Returns Name of Thread
t.setName(newName) ☐ To set our own name

Note: Every Thread has implicit variable "name" to represent name of Thread.

Eg:

```
1) from threading import *
2) print(current_thread().getName())
3) current_thread().setName("Pawan Kalyan")
4) print(current_thread().getName())
5) print(current_thread().name)
```

Output:
MainThread
Pawan
Kalyan
Pawan
Kalyan

Thread Identification Number (ident):

For every thread internally a unique identification number is available. We can access this id byusing implicit variable "ident"

```
1) from threading import *
2) def test():
3)     print("Child Thread")
4) t=Thread(target=test)
```

```
5)  t.start()
6)  print("Main Thread Identification Number:",current_thread().ident)
7)  print("Child Thread Identification Number:",t.ident)
```

Output:
Child Thread
Main Thread Identification Number:
2492Child Thread Identification
Number: 2768

active_count():
This function returns the number of active threads currently running.

Eg:

```
1)  from threading import *
2)  import time
3)  def display():
4)      print(current_thread().getName(),"...started")
5)      time.sleep(3)
6)      print(current_thread().getName(),"...ended")
7)  print("The Number of active Threads:",active_count())
8)  t1=Thread(target=display,name="ChildThread1")
9)  t2=Thread(target=display,name="ChildThread2")
10) t3=Thread(target=display,name="ChildThread3")
11) t1.start()
12) t2.start()
13) t3.start()
14) print("The Number of active Threads:",active_count())
15) time.sleep(5)
16) print("The Number of active Threads:",active_count())
```

Output:
D:\python_classes>py test.py
The Number of active Threads:
1ChildThread1 ...started
ChildThread2 ...started
ChildThread3 ...started
The Number of active Threads:
4ChildThread1 ...ended
ChildThread2 ...ended
ChildThread3 ...ended
The Number of active Threads: 1

enumerate() function:

This function returns a list of all active threads currently running.

Eg:

```python
1)  from threading import *
2)  import time
3)  def display():
4)      print(current_thread().getName(),"...started")
5)      time.sleep(3)
6)      print(current_thread().getName(),"...ended")
7)  t1=Thread(target=display,name="ChildThread1")
8)  t2=Thread(target=display,name="ChildThread2")
9)  t3=Thread(target=display,name="ChildThread3")
10) t1.start()
11) t2.start()
12) t3.start()
13) l=enumerate()
14) for t in l:
15)     print("Thread Name:",t.name)
16) time.sleep(5)
17) l=enumerate()
18) for t in l:
19)     print("Thread Name:",t.name)
```

Output:

D:\python_classes>py
test.pyChildThread1
...started ChildThread2
...started ChildThread3
...started Thread Name:
MainThread Thread Name:
ChildThread1 Thread
Name: ChildThread2
Thread Name:
ChildThread3
ChildThread1 ...ended
ChildThread2 ...ended
ChildThread3 ...ended
Thread Name: MainThread

isAlive():

isAlive() method checks whether a thread is still executing or not.

Eg:

```python
1)  from threading import *
2)  import time
3)  def display():
4)      print(current_thread().getName(),"...started")
5)      time.sleep(3)
6)      print(current_thread().getName(),"...ended")
7)  t1=Thread(target=display,name="ChildThread1")
8)  t2=Thread(target=display,name="ChildThread2")
```

```
9)  t1.start()
10) t2.start()
11)
12) print(t1.name,"is Alive :",t1.isAlive())
13) print(t2.name,"is Alive :",t2.isAlive())
14) time.sleep(5)
15) print(t1.name,"is Alive :",t1.isAlive())
16) print(t2.name,"is Alive :",t2.isAlive())
```

Output:
D:\python_classes>py test.py
ChildThread1 ...started
ChildThread2 ...started
ChildThread1 is Alive :
True ChildThread2 is Alive
: True ChildThread1
...ended ChildThread2
...ended ChildThread1 is
Alive : False ChildThread2
is Alive : False

join() method:

If a thread wants to wait until completing some other thread then we should go for join() method.

Eg:

```
1)  from threading import *
2)  import time
3)  def display():
4)     for i in range(10):
5)        print("Seetha Thread")
6)        time.sleep(2)
7)
8)  t=Thread(target=display)
9)  t.start()
10) t.join()#This Line executed by Main Thread
11) for i in range(10):
12)    print("Rama Thread")
```

In the above example Main Thread waited until completing child thread. In this case

output is:Seetha Thread
Seetha
ThreadSeetha
ThreadSeetha
ThreadSeetha
ThreadSeetha
ThreadSeetha
Thread

Seetha
ThreadSeetha
ThreadSeetha
ThreadRama
Thread Rama
Thread Rama
Thread Rama
Thread Rama
Thread Rama
Thread Rama
Thread Rama
Thread Rama
Thread Rama
Thread Rama
Thread

Note: We can call join() method with time period also.

t.join(seconds)

In this case thread will wait only specified amount of time.

Eg:

```
1) from threading import *
2) import time
3) def display():
4)    for i in range(10):
5)       print("Seetha Thread")
6)       time.sleep(2)
7)
8) t=Thread(target=display)
9) t.start()
10) t.join(5)#This Line executed by Main Thread
11) for i in range(10):
12)    print("Rama Thread")
```

In this case Main Thread waited only 5 seconds.

Output:
Seetha
ThreadSeetha
ThreadSeetha
ThreadRama
Thread Rama
Thread Rama
Thread Rama
Thread Rama
Thread Rama
Thread Rama
Thread

Rama Thread
Rama Thread
Rama Thread
Seetha
ThreadSeetha
ThreadSeetha
ThreadSeetha
ThreadSeetha
ThreadSeetha
ThreadSeetha
Thread

Summary of all methods related to threading module and Thread

Daemon Threads:

The threads which are running in the background are called Daemon Threads.

The main objective of Daemon Threads is to provide support for Non Daemon Threads(like main thread)

Eg: Garbage Collector

Whenever Main Thread runs with low memory, immediately PVM runs Garbage Collector todestroy useless objects and to provide free memory,so that Main Thread can continue its execution without having any memory problems.

We can check whether thread is Daemon or not by using t.isDaemon() method of Thread class orby using daemon property.

Eg:

```
1)  from threading import *
2)  print(current_thread().isDaemon()) #False
3)  print(current_thread().daemon) #False
```

We can change Daemon nature by using setDaemon() method of Thread class.
            t.setDaemon(True)
But we can use this method before starting of Thread.i.e once thread started,we cannot change itsDaemon nature,otherwise we will get
RuntimeException:cannot set daemon status of active thread

Eg:

```
1)  from threading import *
2)  print(current_thread().isDaemon())
```

3) **current_thread().setDaemon(True)**

RuntimeError: cannot set daemon status of active thread

Default Nature:

By default Main Thread is always non-daemon.But for the remaining threads Daemon nature willbe inherited from parent to child.i.e if the Parent Thread is Daemon then child thread is also Daemon and if the Parent Thread is Non Daemon then ChildThread is also Non Daemon.

Eg:

```python
1) from threading import *
2) def job():
3)     print("Child Thread")
4) t=Thread(target=job)
5) print(t.isDaemon())#False
6) t.setDaemon(True)
7) print(t.isDaemon()) #True
```

Note: Main Thread is always Non-Daemon and we cannot change its Daemon Nature b'z it isalready started at the beginning only.

Whenever the last Non-Daemon Thread terminates automatically all Daemon Threads will beterminated.

Eg:

```python
1) from threading import *
2) import time
3) def job():
4)     for i in range(10):
5)         print("Lazy Thread")
6)         time.sleep(2)
7)
8) t=Thread(target=job)
9) #t.setDaemon(True)===>Line-1
10) t.start()
11) time.sleep(5)
12) print("End Of Main Thread")
```

In the above program if we comment Line-1 then both Main Thread and Child Threads are NonDaemon and hence both will be executed until their completion.
In this case output is:

Lazy
Thread
Lazy
Thread
Lazy
Thread

**End   Of   Main
Thread   Lazy
Thread
Lazy
Thread
Lazy
Thread
Lazy
Thread
Lazy
Thread
Lazy
Thread
Lazy
Thread**

**If we are not commenting Line-1 then Main Thread is Non-Daemon and Child Thread is
Daemon.Hence whenever MainThread terminates automatically child thread will be
terminated. In this case output is**

**Lazy
Thread
Lazy
Thread
Lazy
Thread
End of Main Thread**

Synchronization:

**If multiple threads are executing simultaneously then there may be a chance of data
inconsistencyproblems.**

Eg:

```python
1)   from threading import *
2)  import time
3)  def wish(name):
4)     for i in range(10):
5)         print("Good Evening:",end='')
6)         time.sleep(2)
7)         print(name)
8)  t1=Thread(target=wish,args=("Dhoni",))
9)   t2=Thread(target=wish,args=("Yuvraj",))
10) t1.start()
11)  t2.start()
```

Output:
 **Good Evening:Good
Evening:YuvrajDhoni
Good Evening:Good
Evening:YuvrajDhoni
....**

We are getting irregular output b'z both threads are executing simultaneously wish()

function.To overcome this problem we should go for synchronization.

In synchronization the threads will be executed one by one so that we can overcome datainconsistency problems.

Synchronization means at a time only one Thread

The main application areas of synchronization are
1. Online Reservation system
2. Funds Transfer from joint
accountsetc

In Python, we can implement synchronization by using the following
1. Lock
2. RLock
3. Semaphore

Synchronization By using Lock concept:

Locks are the most fundamental synchronization mechanism provided by threading module.
We can create Lock object as
followsl=Lock()

The Lock object can be hold by only one thread at a time.If any other thread required the same lock then it will wait until thread releases lock.(similar to common wash rooms,public telephone booth etc)

A Thread can acquire the lock by using acquire()
method.l.acquire()

A Thread can release the lock by using release()
method.l.release()

Note: To call release() method compulsory thread should be owner of that lock.i.e thread should has the lock already,otherwise we will get Runtime Exception saying
RuntimeError: release unlocked lock

Eg:

```
1)  from threading import *
2)  l=Lock()
3)  #l.acquire() ==>1
4)   l.release()
```

If we are commenting line-1 then we will
getRuntimeError: release unlocked lock

Eg:

```
1)   from threading import *
```

```
 2)  import time
 3)  l=Lock()
 4)  def wish(name):
 5)      l.acquire()
 6)      for i in range(10):
 7)          print("Good Evening:",end='')
 8)          time.sleep(2)
 9)          print(name)
10)      l.release()
11)
12)  t1=Thread(target=wish,args=("Dhoni",))
13)  t2=Thread(target=wish,args=("Yuvraj",))
14)  t3=Thread(target=wish,args=("Kohli",))
15)  t1.start()
16)  t2.start()
17)  t3.start()
```

In the above program at a time only one thread is allowed to execute wish() method and hence wewill get regular output.

Problem with Simple Lock:

The standard Lock object does not care which thread is currently holding that lock.If the lock isheld and any thread attempts to acquire lock, then it will be blocked,even the same thread is already holding that lock.

Eg:

```
 1)  from threading import *
 2)  l=Lock()
 3)  print("Main Thread trying to acquire Lock")
 4)  l.acquire()
 5)  print("Main Thread trying to acquire Lock Again")
 6)  l.acquire()
```

Output:
D:\python_classes>py test.py
Main Thread trying to acquire
Lock
Main Thread trying to acquire Lock Again
--
In the above Program main thread will be blocked b'z it is trying to acquire the lock second time.

Note: To kill the blocking thread from windows command prompt we have to use ctrl+break. Herectrl+C won't work.

If the Thread calls recursive functions or nested access to resources,then the thread may trying toacquire the same lock again and again,which may block our thread.

Hence Traditional Locking mechanism won't work for executing recursive functions.

To overcome this problem, we should go for RLock(Reentrant Lock). Reentrant means the thread can acquire the same lock again and again.If the lock is held by other threads then only the threadwill be blocked.
Reentrant facility is available only for owner thread but not for other threads.

Eg:

```
1)  from threading import *
2)  l=RLock()
3)  print("Main Thread trying to acquire Lock")
4)  l.acquire()
5)  print("Main Thread trying to acquire Lock Again")
6)  l.acquire()
```

In this case Main Thread won't be Locked b'z thread can acquire the lock any number of times.

This RLock keeps track of recursion level and hence for every acquire() call compulsory release()call should be available. i.e the number of acquire() calls and release() calls should be matched then only lock will be released.

Eg:
```
l=RLock(
)
l.acquire(
)
l.acquire(
)
l.release()
l.release()
```

After 2 release() calls only the Lock will be released.

Note:
1. Only owner thread can acquire the lock multiple times
2. The number of acquire() calls and release() calls should be matched.

Demo Program for synchronization by using RLock:

```
1)   from threading import *
2)  import time
3)   l=RLock()
4)  def factorial(n):
5)      l.acquire()
6)      if n==0:
7)         result=1
8)      else:
9)         result=n*factorial(n-1)
10)     l.release()
11)     return result
```

```
12)
13) def results(n):
14)    print("The Factorial of",n,"is:",factorial(n))
15)
16) t1=Thread(target=results,args=(5,))
17) t2=Thread(target=results,args=(9,))
18) t1.start()
19) t2.start()
```

Output:
The Factorial of 5 is: 120
The Factorial of 9 is: 362880

In the above program instead of RLock if we use normal Lock then the thread will be blocked.

Difference between Lock and RLock:
table

Lock:

1. Lock object can be acquired by only one thread at a time.Even owner thread also cannot acquiremultiple times.
2. Not suitable to execute recursive functions and nested access calls
3. In this case Lock object will takes care only Locked or unlocked and it never takes care aboutowner thread and recursion level.

RLock:

1. RLock object can be acquired by only one thread at a time, but owner thread can acquire samelock object multiple times.
2. Best suitable to execute recursive functions and nested access calls
3. In this case RLock object will takes care whether Locked or unlocked and owner threadinformation, recursiion level.

Synchronization by using Semaphore:

In the case of Lock and RLock,at a time only one thread is allowed to execute.

Sometimes our requirement is at a time a particular number of threads are allowed to access(likeat a time 10 memebers are allowed to access database server,4 members are allowed to access Network connection etc).To handle this requirement we cannot use Lock and RLock concepts andwe should go for Semaphore concept.

Semaphore can be used to limit the access to the shared resources with limited capacity.

Semaphore is advanced Synchronization Mechanism.

We can create Semaphore object as follows.

s=Semaphore(counter)

Here counter represents the maximum number of threads are allowed to access simultaneously.The default value of counter is 1.

Whenever thread executes acquire() method,then the counter value will be decremented by 1 andif thread executes release() method then the counter value will be incremented by 1.

i.e for every acquire() call counter value will be decremented and for every release() call counter value will be incremented.

Case-1: s=Semaphore()
In this case counter value is 1 and at a time only one thread is allowed to access. It is exactly sameas Lock concept.

Case-2: s=Semaphore(3)
In this case Semaphore object can be accessed by 3 threads at a time.The remaining threads haveto wait until releasing the semaphore.

Eg:

```python
1)   from threading import *
2)   import time
3)   s=Semaphore(2)
4)   def wish(name):
5)       s.acquire()
6)       for i in range(10):
7)           print("Good Evening:",end='')
8)           time.sleep(2)
9)           print(name)
10)      s.release()
11)
12) t1=Thread(target=wish,args=("Dhoni",))
13) t2=Thread(target=wish,args=("Yuvraj",))
14) t3=Thread(target=wish,args=("Kohli",))
15) t4=Thread(target=wish,args=("Rohit",))
16) t5=Thread(target=wish,args=("Pandya",))
17) t1.start()
18) t2.start()
19) t3.start()
20) t4.start()
21) t5.start()
```

n the above program at a time 2 threads are allowed to access semaphore and hence 2 threadsare allowed to execute wish() function.

BoundedSemaphore:

Normal Semaphore is an unlimited semaphore which allows us to call release() method any number of times to increment counter.The number of release() calls can exceed the number ofacquire() calls also.

Eg:

```
1)  from threading import *
2) s=Semaphore(2)
3)   s.acquire()
4) s.acquire()
5)   s.release()
6) s.release()
7)   s.release()
8) s.release()
9)   print("End")
```

It is valid because in normal semaphore we can call release() any number of times.

BounedSemaphore is exactly same as Semaphore except that the number of release() calls shouldnot exceed the number of acquire() calls,otherwise we will get

ValueError: Semaphore released too many times

Eg:

```
1)  from threading import *
2) s=BoundedSemaphore(2)
3)   s.acquire()
4) s.acquire()
5)   s.release()
6) s.release()
7)   s.release()
8) s.release()
9)  print("End")
```

ValueError: Semaphore released too many times
It is invalid b'z the number of release() calls should not exceed the number of acquire() calls in BoundedSemaphore.

Note: To prevent simple programming mistakes, it is recommended to use BoundedSemaphore over normal Semaphore.

Difference between Lock and Semaphore:

At a time Lock object can be acquired by only one thread, but Semaphore object can be acquiredby fixed number of threads specified by counter value.

Conclusion:

The main advantage of synchronization is we can overcome data inconsistency problems.But themain disadvantage of synchronization is it increases waiting time of threads and creates performance problems. Hence if there is no specific requirement then it is not recommended to use synchronization.

Inter Thread Communication:

Some times as the part of programming requirement, threads are required to communicate witheach other. This concept is nothing but interthread communication.

Eg: After producing items Producer thread has to communicate with Consumer thread to notify about new item.Then consumer thread can consume that new item.

In Python, we can implement interthread communication by using the following ways

1. Event
2. Condition
3. Queue
etc

Interthread communication by using Event Objects:

Event object is the simplest communication mechanism between the threads. One thread signalsan event and other thereds wait for it.

We can create Event object as follows...

event = threading.Event()

Event manages an internal flag that can set() or clear()
Threads can wait until event set.

Methods of Event class:

1.set() internal flag value will become True and it represents GREEN signal for all waitingthreads.

2. clear() inernal flag value will become False and it represents RED signal for all waitingthreads.

3. isSet() This method can be used whether the event is set or not

4. wait()|wait(seconds) ☐ Thread can wait until event is set

Pseudo Code:

event = threading.Event()

#consumer thread has to wait until event is
setevent.wait()

#producer thread can set or clear
eventevent.set()
event.clear()

Demo Program-1:

```python
1)  from threading import *
2)  import time
3)  def producer():
4)      time.sleep(5)
5)      print("Producer thread producing items:")
6)      print("Producer thread giving notification by setting event")
7)      event.set()
8)  def consumer():
9)      print("Consumer thread is waiting for updation")
10)     event.wait()
11)     print("Consumer thread got notification and consuming items")
12)
13) event=Event()
14) t1=Thread(target=producer)
15) t2=Thread(target=consumer)
16) t1.start()
17) t2.start()
```

Output:
Consumer thread is waiting for
updationProducer thread producing
items
Producer thread giving notification by setting event
Consumer thread got notification and consuming items

Demo Program-2:

```python
1)  from threading import *
2)  import time
3)  def trafficpolice():
4)      while True:
5)          time.sleep(10)
6)          print("Traffic Police Giving GREEN Signal")
```

```
7)        event.set()
8)        time.sleep(20)
9)        print("Traffic Police Giving RED Signal")
10)       event.clear()
11) def driver():
12)    num=0
13)    while True:
14)       print("Drivers waiting for GREEN Signal")
15)       event.wait()
16)       print("Traffic Signal is GREEN...Vehicles can move")
17)       while event.isSet():
18)          num=num+1
19)          print("Vehicle No:",num,"Crossing the Signal")
20)          time.sleep(2)
21)       print("Traffic Signal is  RED...Drivers have to wait")
22) event=Event()
23) t1=Thread(target=trafficpolice)
24) t2=Thread(target=driver)
25) t1.start()
26) t2.start()
```

In the above program driver thread has to wait until Trafficpolice thread sets event.ie until giving GREEN signal.Once Traffic police thread sets event(giving GREEN signal),vehicles can cross the signal.Once traffic police thread clears event (giving RED Signal)then the driver thread has to wait.

Interthread communication by using Condition Object:

Condition is the more advanced version of Event object for interthread communication.A condition represents some kind of state change in the application like producing item or consuming item. Threads can wait for that condition and threads can be notified once condition happend.i.e Condition object allows one or more threads to wait until notified by another thread.

Condition is always associated with a lock (ReentrantLock).
A condition has acquire() and release() methods that call the corresponding methods of the associated lock.

We can create Condition object as
followscondition = threading.Condition()

Methods of Condition:

1. acquire() 🡒 To acquire Condition object before producing or consuming items.i.e threadacquiring internal lock.

2. release() 🡒 To release Condition object after producing or consuming items. i.e thread releasesinternal lock

3. wait()|wait(time) 🡒 To wait until getting Notification or time expired

4. notify() ☐ To give notification for one waiting thread

5. notifyAll() ☐ To give notification for all waiting threads

Case Study:

The producing thread needs to acquire the Condition before producing item to the resource andnotifying the consumers.

#Producer Thread
...generate item..
condition.acquire(
)
...add item to the resource...
condition.notify()#signal that a new item is
available(notifyAll())condition.release()

The Consumer must acquire the Condition and then it can consume items from the

resource#Consumer Thread
condition.acquire(
)condition.wait()
consume item
condition.release()

Demo Program-1:

```
1)  from threading import *
2)  def consume(c):
3)      c.acquire()
4)      print("Consumer waiting for updation")
5)      c.wait()
6)      print("Consumer got notification & consuming the item")
7)      c.release()
8)
9)  def produce(c):
10)     c.acquire()
11)     print("Producer Producing Items")
12)     print("Producer giving Notification")
13)     c.notify()
14)     c.release()
15)
16) c=Condition()
17) t1=Thread(target=consume,args=(c,))
18) t2=Thread(target=produce,args=(c,))
19) t1.start()
20) t2.start()
```

Output:
Consumer waiting for
updationProducer Producing
Items Producer giving
Notification
Consumer got notification & consuming the item

Demo Program-2:

```python
1)  from threading import *
2)  import time
3)  import random
4)  items=[]
5)  def produce(c):
6)     while True:
7)         c.acquire()
8)         item=random.randint(1,100)
9)         print("Producer Producing Item:",item)
10)        items.append(item)
11)        print("Producer giving Notification")
12)        c.notify()
13)        c.release()
14)        time.sleep(5)
15)
16) def consume(c):
17)    while True:
18)        c.acquire()
19)        print("Consumer waiting for updation")
20)        c.wait()
21)        print("Consumer consumed the item",items.pop())
22)        c.release()
23)        time.sleep(5)
24)
25) c=Condition()
26) t1=Thread(target=consume,args=(c,))
27) t2=Thread(target=produce,args=(c,))
28) t1.start()
29) t2.start()
```

Output:
Consumer waiting for updation
Producer Producing Item: 49
Producer giving Notification
Consumer consumed the item
49
.....

In the above program Consumer thread expecting updation and hence it is responsible to callwait() method on Condition object.
Producer thread performing updation and hence it is responsible to call notify() or notifyAll() onCondition object.

Interthread communication by using Queue:

Queues Concept is the most enhanced Mechanism for interthread communication and to share data between threads.

Queue internally has Condition and that Condition has Lock.Hence whenever we are using Queuewe are not required to worry about Synchronization.

If we want to use Queues first we should import queue

module.import queue

We can create Queue object as follows

```
q = queue.Queue()
```

Important Methods of Queue:

1. **put():** Put an item into the queue.
2. **get():** Remove and return an item from the queue.

Producer Thread uses put() method to insert data in the queue. Internally this method has logic to acquire the lock before inserting data into queue. After inserting data lock will be released automatically.

put() method also checks whether the queue is full or not and if queue is full then the Producer thread will entered in to waiting state by calling wait() method internally.

Consumer Thread uses get() method to remove and get data from the queue. Internally this method has logic to acquire the lock before removing data from the queue.Once removal completed then the lock will be released automatically.

If the queue is empty then consumer thread will entered into waiting state by calling wait() method internally.Once queue updated with data then the thread will be notified automatically.

Note:
The queue module takes care of locking for us which is a great advantage.

Eg:

```
1)  from threading import *
2)  import time
3)  import random
4)  import queue
5)  def produce(q):
```

```
 6)    while True:
 7)      item=random.randint(1,100)
 8)      print("Producer Producing Item:",item)
 9)      q.put(item)
10)      print("Producer giving Notification")
11)      time.sleep(5)
12) def consume(q):
13)    while True:
14)      print("Consumer waiting for updation")
15)      print("Consumer consumed the item:",q.get())
16)      time.sleep(5)
17)
18) q=queue.Queue()
19) t1=Thread(target=consume,args=(q,))
20) t2=Thread(target=produce,args=(q,))
21) t1.start()
22) t2.start()
```

Output:
Consumer waiting for updation
Producer Producing Item: 58
Producer giving Notification
Consumer consumed the item:
58

Types of Queues:

Python Supports 3 Types of Queues.

1. FIFO Queue:

q = queue.Queue()

This is Default Behaviour. In which order we put items in the queue, in the same order the itemswill come out (FIFO-First In First Out).

Eg:

```
1) import queue
2) q=queue.Queue()
3)  q.put(10)
4) q.put(5)
5)  q.put(20)
6)  q.put(15)
7) while not q.empty():
8)    print(q.get(),end=' ')
```

Output: **10 5 20   15**

2. LIFO Queue:

The removal will be happend in the reverse order of insertion(Last In First Out)

Eg:

```
1)  import queue
2)  q=queue.LifoQueue()
3)   q.put(10)
4)  q.put(5)
5)   q.put(20)
6)   q.put(15)
7)  while not q.empty():
8)     print(q.get(),end=' ')
```

Output: 15 20   5   10

3. Priority Queue:

The elements will be inserted based on some priority order.

```
1)  import queue
2)  q=queue.PriorityQueue()
3)   q.put(10)
4)  q.put(5)
5)   q.put(20)
6)   q.put(15)
7)  while not q.empty():
8)     print(q.get(),end=' ')
```

Output: 5 10   15   20

Eg 2: If the data is non-numeric, then we have to provide our data in the form of tuple.

(x,y)

x is priority
y is our element

```
1)   import queue
2)  q=queue.PriorityQueue()
3)   q.put((1,"AAA"))
4)   q.put((3,"CCC"))
5)   q.put((2,"BBB"))
6)  q.put((4,"DDD"))
7)  while not q.empty():
8)     print(q.get()[1],end=' ')
```

Output: AAA BBB CCC DDD

Good Programming Practices with usage of Locks:

Case-1:

It is highly recommended to write code of releasing locks inside finally block.The advantage is lockwill be released always whether exception raised or not raised and whether handled or not handled.

l=threading.Lock
()l.acquire()
try:
        perform required safe
finally
:   **operationsl.release()**

Demo Program:

```python
1)  from threading import *
2)  import time
3)  l=Lock()
4)  def wish(name):
5)    l.acquire()
6)    try:
7)      for i in range(10):
8)        print("Good Evening:",end='')
9)        time.sleep(2)
10)       print(name)
11)   finally:
12)     l.release()
13)
14) t1=Thread(target=wish,args=("Dhoni",))
15) t2=Thread(target=wish,args=("Yuvraj",))
16) t3=Thread(target=wish,args=("Kohli",))
17) t1.start()
18) t2.start()
19) t3.start()
```

Case-2:

It is highly recommended to acquire lock by using with statement. The main advantage of with statement is the lock will be released automatically once control reaches end of with block and weare not required to release explicitly.

his is exactly same as usage of with statement for files.

Example for File:

```
with open('demo.txt','w') as f:
    f.write("Hello...")
```

Example for Lock:

```
lock=threading.Lock
()with lock:
        perform required safe operations
        lock will be released
        automatically
```

Demo Program:

```python
1)   from threading import *
2)  import time
3)  lock=Lock()
4)  def wish(name):
5)     with lock:
6)        for i in range(10):
7)           print("Good Evening:",end='')
8)           time.sleep(2)
9)           print(name)
10) t1=Thread(target=wish,args=("Dhoni",))
11) t2=Thread(target=wish,args=("Yuvraj",))
12) t3=Thread(target=wish,args=("Kohli",))
13) t1.start()
14) t2.start()
15) t3.start()
```

Q. What is the advantage of using with statement to acquire a lock in threading?

Lock will be released automatically once control reaches end of with block and We are notrequired to release explicitly.

Note: We can use with statement in multithreading for the following cases:

1. Lock
2. RLock
3. Semaphore
4. Condition

Python Database Programming

Storage Areas

As the Part of our Applications, we required to store our Data like Customers Information, Billing Information, Calls Information etc..

To store this Data, we required Storage Areas. There are 2 types of Storage Areas.

1) Temporary Storage Areas
2) Permanent Storage Areas

1.Temporary Storage Areas:

These are the Memory Areas where Data will be stored temporarily.
Eg: Python objects like List, Tuple, Dictionary.

Once Python program completes its execution then these objects will be destroyed automatically and data will be lost.

2. Permanent Storage Areas:

Also known as Persistent Storage Areas. Here we can store Data permanently.
Eg: File Systems, Databases, Data warehouses, Big Data Technologies etc

File Systems:

File Systems can be provided by Local operating System. File Systems are best suitable to store very less Amount of Information.

Limitations:

1) We cannot store huge Amount of Information.
2) There is no Query Language support and hence operations will become very complex.
3) There is no Security for Data.
4) There is no Mechanism to prevent duplicate Data. Hence there may be a chance of DataInconsistency Problems.

To overcome the above Problems of File Systems, we should go for Databases.

Databases:

1) We can store Huge Amount of Information in the Databases.

2) Query Language Support is available for every Database and hence we can perform DatabaseOperations very easily.

3) To access Data present in the Database, compulsory username and pwd must be required.Hence Data is secured.

4) Inside Database Data will be stored in the form of Tables. While developing Database Table Schemas, Database Admin follow various Normalization Techniques and can implement variousConstraints like Unique Key Constrains, Primary Key Constraints etc which prevent Data Duplication. Hence there is no chance of Data Inconsistency Problems.

Limitations of Databases:

1) Database cannot hold very Huge Amount of Information like Terabytes of Data.

2) Database can provide support only for Structured Data (Tabular Data OR Relational Data) andcannot provide support for Semi Structured Data (like XML Files) and Unstructured Data (like Video Files, Audio Files, Images etc)

To overcome these Problems we should go for more Advanced Storage Areas like Big Data Technologies, Data warehouses etc.

Python Database Programming:

 Sometimes as the part of Programming requirement we have to connect to the database and wehave to perform several operations like creating tables, inserting data,updating data,deleting data,selecting data etc.

We can use SQL Language to talk to the database and we can use Python to send those SQLcommands to the database.

Python provides inbuilt support for several databases like Oracle, MySql, SqlServer, GadFly, sqlite,etc.
Python has seperate module for each database.
Eg: cx_Oralce module for communicating with Oracle database
     pymssql module for communicating with Microsoft Sql
     Server

Standard Steps for Python database Programming:

1. Import database specific module
  Eg: import cx_Oracle

2. Establish Connection between Python Program and database.
  We can create this Connection object by using connect() function of the
  module.con = cx_Oracle.connect(datbase information)

  Eg: con=cx_Oracle.connect('scott/tiger@localhost')

3. To execute our sql queries and to hold results some special object is required, which is nothingbut Cursor object. We can create Cursor object by using cursor() method.

cursor=con.cursor()

4. Execute SQL Queries By using Cursor object. For this we can use the following methods

 i) execute(sqlquery) ☐ To execute a single sql query
 ii) executescript(sqlqueries) ☐ To execute a string of sql queries seperated by semi-colon ';'
 iii) executemany() ☐ To execute a Parameterized query

 Eg: **cursor.execute("select * from employees")**

5. commit or rollback changes based on our requirement in the case of DMLQueries(insert|update|delete)

 commit() ☐ Saves the changes to the database
 rollback() ☐ rolls all temporary changes back

6. Fetch the result from the Cursor object in the case of select
 queriesfetchone() ☐ To fetch only one row
 fetchall() ☐ To fetch all rows and it returns a list of rows
 fecthmany(n) ☐ To fetch first n rows

 Eg 1: data
   =cursor.fetchone()
   print(data)

 Eg 2:
   data=cursor.fetchall()
   for row in data:
        print(row)

7. close the resources
  After completing our operations it is highly recommended to close the resources in the reverseorder of their opening by using close() methods.

 cursor.close(
)con.close()

 Note: **The following is the list of all important methods which can be used for python databaseprogramming.**

onnect()
cursor()
execute()
executescript()
executemany()
commit()
rollback()
fetchone()
fetchall()
fetchmany(n)

fetch
close()

These methods won't be changed from database to database and same for all databases.

Working with Oracle Database:

From Python Program if we want to communicate with any database,some translator must berequired to translate Python calls into Database specific calls and Database specific calls into Python calls.This translator is nothing but Driver/Connector.

Diagram

For Oracle database the name of driver needed is cx_Oracle.
cx_Oracle is a Python extension module that enables access to Oracle Database.It can be used forboth Python2 and Python3. It can work with any version of Oracle database like 9,10,11 and 12.

Installing cx_Oracle:

From Normal Command Prompt (But not from Python console)execute the following

commandD:\python_classes>pip install cx_Oracle

 Collecting cx_Oracle
  Downloading cx_Oracle-6.0.2-cp36-cp36m-win32.whl
    (100kB)100% | | 102kB 256kB/s
Installing collected packages: cx-
OracleSuccessfully installed cx-
Oracle-6.0.2

How to Test Installation:

From python console execute the following command:

>>> help("modules")

In the output we can see cx_Oracle

.....

App1: Program to connect with Oracle database and print its version.

```python
1)   import cx_Oracle
2)   con=cx_Oracle.connect('scott/tiger@localhost')
3)   print(con.version)
4)   con.close()
```

Output:
D:\python_classes>py
db1.py11.2.0.2.0

App2: Write a Program to create employees table in the oracle database :
employees(eno,ename,esal,eaddr)

```python
1)   import cx_Oracle
2)   try:
3)       con=cx_Oracle.connect('scott/tiger@localhost')
4)       cursor=con.cursor()
5)       cursor.execute("create table employees(eno number,ename varchar2(10),esal number(10,2),eaddr varchar2(10))")
6)       print("Table created successfully")
7)   except cx_Oracle.DatabaseError as e:
8)       if con:
9)           con.rollback()
10)          print("There is a problem with sql",e)
11)  finally:
12)      if cursor:
13)          cursor.close()
14)      if con:
15)          con.close()
```

App3: Write a program to drop employees table from oracle database?

```python
1)   import cx_Oracle
2)   try:
3)       con=cx_Oracle.connect('scott/tiger@localhost')
4)       cursor=con.cursor()
5)       cursor.execute("drop table employees")
6)       print("Table dropped successfully")
7)   except cx_Oracle.DatabaseError as e:
8)       if con:
9)           con.rollback()
10)          print("There is a problem with sql",e)
11)  finally:
12)      if cursor:
13)          cursor.close()
14)      if con:
15)          con.close()
```

App3: Write a program to insert a single row in the employees table.

```
1)   import cx_Oracle
2)   try:
3)       con=cx_Oracle.connect('scott/tiger@localhost')
4)       cursor=con.cursor()
5)       cursor.execute("insert into employees values(100,'Durga',1000,'Hyd')")
6)       con.commit()
7)       print("Record Inserted Successfully")
8)   except cx_Oracle.DatabaseError as e:
9)       if con:
10)          con.rollback()
11)          print("There is a problem with sql",e)
12)  finally:
13)      if cursor:
14)          cursor.close()
15)      if con:
16)          con.close()
```

Note: While performing DML Operations (insert|update|delte), compulsory we have to usecommit() method,then only the results will be reflected in the database.

App4: Write a program to insert multiple rows in the employees table byusing executemany() method.

```
1)   import cx_Oracle
2)   try:
3)       con=cx_Oracle.connect('scott/tiger@localhost')
4)       cursor=con.cursor()
5)       sql="insert into employees values(:eno,:ename,:esal,:eaddr)"
6)       records=[(200,'Sunny',2000,'Mumbai'),
7)                (300,'Chinny',3000,'Hyd'),
8)                (400,'Bunny',4000,'Hyd')]
9)       cursor.executemany(sql,records)
10)      con.commit()
11)      print("Records Inserted Successfully")
12)  except cx_Oracle.DatabaseError as e:
13)      if con:
14)          con.rollback()
15)          print("There is a problem with sql",e)
16)  finally:
17)      if cursor:
18)          cursor.close()
19)      if con:
20)          con.close()
```

App5: Write a program to insert multiple rows in the employees table with dynamic input from the keyboard?

```
1)   import cx_Oracle
2)   try:
3)       con=cx_Oracle.connect('scott/tiger@localhost')
4)       cursor=con.cursor()
5)       while True:
6)           eno=int(input("Enter Employee Number:"))
7)           ename=input("Enter Employee Name:")
8)           esal=float(input("Enter Employee Salary:"))
9)           eaddr=input("Enter Employee Address:")
10)          sql="insert into employees values(%d,'%s',%f,'%s')"
11)          cursor.execute(sql %(eno,ename,esal,eaddr))
12)          print("Record Inserted Successfully")
13)          option=input("Do you want to insert one more record[Yes|No] :")
14)          if option=="No":
15)              con.commit()
16)              break
17)  except cx_Oracle.DatabaseError as e:
18)      if con:
19)          con.rollback()
20)          print("There is a problem with sql :",e)
21)  finally:
22)      if cursor:
23)          cursor.close()
24)      if con:
25)          con.close()
```

App6: Write a program to update employee salaries with increment for the certain range with dynamic input.

Eg: Increment all employee salaries by 500 whose salary < 5000

```
1)   import cx_Oracle
2)   try:
3)       con=cx_Oracle.connect('scott/tiger@localhost')
4)       cursor=con.cursor()
5)       increment=float(input("Enter Increment Salary:"))
6)       salrange=float(input("Enter Salary Range:"))
7)       sql="update employees set esal=esal+%f where esal<%f"
8)       cursor.execute(sql %(increment,salrange))
9)       print("Records Updated Successfully")
10)      con.commit()
11)  except cx_Oracle.DatabaseError as e:
12)      if con:
13)          con.rollback()
14)          print("There is a problem with sql :",e)
15)  finally:
16)      if cursor:
17)          cursor.close()
18)      if con:
19)          con.close()
```

App7: Write a program to delete employees whose salary greater provided salary as dynamic input?

Eg: delete all employees whose salary > 5000

```
1)   import cx_Oracle
2)   try:
3)       con=cx_Oracle.connect('scott/tiger@localhost')
4)       cursor=con.cursor()
5)       cutoffsalary=float(input("Enter CutOff Salary:"))
6)       sql="delete from employees where esal>%f"
7)       cursor.execute(sql %(cutoffsalary))
8)       print("Records Deleted Successfully")
9)       con.commit()
10)  except cx_Oracle.DatabaseError as e:
11)      if con:
12)          con.rollback()
13)          print("There is a problem with sql :",e)
14)  finally:
15)      if cursor:
16)          cursor.close()
17)      if con:
18)          con.close()
```

App8: Write a program to select all employees info by using fetchone() method?

```
1)   import cx_Oracle
2)   try:
3)       con=cx_Oracle.connect('scott/tiger@localhost')
4)       cursor=con.cursor()
5)       cursor.execute("select * from employees")
6)       row=cursor.fetchone()
7)       while row is not None:
8)           print(row)
9)           row=cursor.fetchone()
10)  except cx_Oracle.DatabaseError as e:
11)      if con:
12)          con.rollback()
13)          print("There is a problem with sql :",e)
14)  finally:
15)      if cursor:
16)          cursor.close()
17)      if con:
18)          con.close()
```

App9: Write a program to select all employees info by using fetchall() method?

```
1)   import cx_Oracle
2)   try:
3)       con=cx_Oracle.connect('scott/tiger@localhost')
4)       cursor=con.cursor()
5)       cursor.execute("select * from employees")
6)       data=cursor.fetchall()
7)       for row in data:
8)           print("Employee Number:",row[0])
9)           print("Employee Name:",row[1])
10)          print("Employee Salary:",row[2])
11)          print("Employee Address:",row[3])
12)          print()
13)          print()
14)  except cx_Oracle.DatabaseError as e:
15)      if con:
16)          con.rollback()
17)          print("There is a problem with sql :",e)
18)  finally:
19)      if cursor:
20)          cursor.close()
21)      if con:
22)          con.close()
```

App10: Write a program to select employees info by using fetchmany() method and the required number of rows will be provided as dynamic input?

```
1)   import cx_Oracle
2)   try:
3)       con=cx_Oracle.connect('scott/tiger@localhost')
4)       cursor=con.cursor()
5)       cursor.execute("select * from employees")
6)       n=int(input("Enter the number of required rows:"))
7)       data=cursor.fetchmany(n)
8)       for row in data:
9)           print(row)
10)  except cx_Oracle.DatabaseError as e:
11)      if con:
12)          con.rollback()
13)          print("There is a problem with sql :",e)
14)  finally:
15)      if cursor:
16)          cursor.close()
17)      if con:
18)          con.close()
```

Output:
D:\python_classes>py test.py
Enter the number of required
rows:3(100, 'Durga', 1500.0, 'Hyd')
(200, 'Sunny', 2500.0, 'Mumbai')
(300, 'Chinny', 3500.0, 'Hyd')

D:\python_classes>py test.py
Enter the number of required
rows:4(100, 'Durga', 1500.0, 'Hyd')
(200, 'Sunny', 2500.0, 'Mumbai')
(300, 'Chinny', 3500.0, 'Hyd')
(400, 'Bunny', 4500.0, 'Hyd')

Working with Mysql database:
Current version: 5.7.19
Vendor: SUN Micro Systems/Oracle Corporation

Open Source and FreewareDefault Port: 3306
Default user: root

Note: In MySQL, everything we have to work with our own databases, which are also known asLogical Databases.

The following are 4 default databases available in mysql.
 1. information_schema
 2. mysql
 3. performance_schema
 4. test

Diagra

m

In the above diagram only one physical database is available and 4 logical databases are available.

Commonly used commands in MySql:

1. To know available databases:
mysql> show databases;

2. To create our own logical database
 mysql> create database durgadb;

3. To drop our own database:
mysql> drop database durgadb;

4. To use a particular logical database
mysql> use durgadb;   OR   mysql> connect durgadb;

 5. To create a table:
 create table employees(eno int(5) primary key,ename varchar(10),esal double(10,2),eaddrvarchar(10));

 6. To insert data:
 insert into employees values(100,'Durga',1000,'Hyd');
 insert into employees values(200,'Ravi',2000,'Mumbai');

 In MySQL instead of single quotes we can use double quotes also.

Driver/Connector Information:

 From Python program if we want to communicates with MySql database,compulsory some translator is required to convert python specific calls into mysql database specific calls and mysql database specific calls into python specific calls. This translator is nothing but Driver or Connector.

Diagram

We have to download connector seperately from mysql

database.

https://dev.mysql.com/downloads/connector/python/2.1.html

How to check installation:

From python console we have to
usehelp("modules")

In the list of modules,compulsory mysql should be there.

Note: **In the case of Python3.4 we have to set PATH and PYTHONPATH explicitly**

PATH=C:\Python34
PYTHONPATH=C:\Python34\Lib\site-packages

Q. Write a Program to create table,insert data and display data by using mysql database.

```
1)   import mysql.connector
2)   try:
3)       con=mysql.connector.connect(host='localhost',database='durgadb',user='root',password='root')
4)       cursor=con.cursor()
5)       cursor.execute("create table employees(eno int(5) primary key,ename varchar(10),esal double(10,2),eaddr varchar(
     10))")
6)       print("Table Created...")
7)
8)       sql = "insert into employees(eno, ename, esal, eaddr) VALUES(%s, %s, %s, %s)"
9)       records=[(100,'Sachin',1000,'Mumbai'),
10)                (200,'Dhoni',2000,'Ranchi'),
11)                (300,'Kohli',3000,'Delhi')]
12)      cursor.executemany(sql,records)
13)      con.commit()
14)      print("Records Inserted Successfully...")
15)
16)      cursor.execute("select * from employees")
17)      data=cursor.fetchall()
18)      for row in data:
19)          print("Employee Number:",row[0])
20)          print("Employee Name:",row[1])
21)          print("Employee Salary:",row[2])
22)          print("Employee Address:",row[3])
23)          print()
24)          print()
25)  except mysql.connector.DatabaseError as e:
26)      if con:
27)          con.rollback()
28)          print("There is a problem with sql :",e)
29)  finally:
30)      if cursor:
31)          cursor.close()
32)      if con:
33)          con.close()
```

Q. Write a Program to copy data present in employees table of mysql database into Oracledatabase.

```
1)   import mysql.connector
2)   import cx_Oracle
3)   try:
4)       con=mysql.connector.connect(host='localhost',database='durgadb',user='root',password='root')
```

```python
5)      cursor=con.cursor()
6)      cursor.execute("select * from employees")
7)      data=cursor.fetchall()
8)      list=[]
9)      for row in data:
10)         t=(row[0],row[1],row[2],row[3])
11)         list.append(t)
12) except mysql.connector.DatabaseError as e:
13)     if con:
14)         con.rollback()
15)         print("There is a problem with MySql :",e)
16) finally:
17)     if cursor:
18)         cursor.close()
19)     if con:
20)         con.close()
21)
22) try:
23)     con=cx_Oracle.connect('scott/tiger@localhost')
24)     cursor=con.cursor()
25)     sql="insert into employees values(:eno,:ename,:esal,:eaddr)"
26)     cursor.executemany(sql,list)
27)     con.commit()
28)     print("Records Copied from MySQL Database to  Oracle Database  Successfully")
29) except cx_Oracle.DatabaseError as e:
30)     if con:
31)         con.rollback()
32)         print("There is a problem with sql",e)
33) finally:
34)     if cursor:
35)         cursor.close()
36)     if con:
37)         con.close()
```

https://dev.mysql.com/downloads/connector/python/2.1.html

```sql
1)  create table employees(eno int(5) primary key,ename varchar(10),esal double(10,2),eaddr varchar(10));
2)
3)   insert into employees values(100,'Durga',1000,'Hyd');
4)   insert into employees values(200,'Ravi',2000,'Mumbai');
5)   insert into employees values(300,'Shiva',3000,'Hyd');
```

Pattern Programs

Pattern-1:

```
* * * * * * * * * *
* * * * * * * * * *
* * * * * * * * * *
* * * * * * * * * *
* * * * * * * * * *
* * * * * * * * * *
* * * * * * * * * *
* * * * * * * * * *
* * * * * * * * * *
* * * * * * * * * *
```

```python
1)  n=int(input("Enter the number of rows: "))
2)  for i in range(1,n+1):
3)      print("* "*n)
```

Pattern-2:

```
1 1 1 1 1 1 1 1 1 1
2 2 2 2 2 2 2 2 2 2
3 3 3 3 3 3 3 3 3 3
4 4 4 4 4 4 4 4 4 4
5 5 5 5 5 5 5 5 5 5
6 6 6 6 6 6 6 6 6 6

Python Loggin g

Module

Python Logging

It is highly recommended to store complete application flow and exceptions information to a file.This process is called logging.

The main advanatages of logging are:

1. We can use log files while performing debugging
2. We can provide statistics like number of requests per day

etcTo implement logging, Python provides inbuilt module

logging.

Logging Levels:

Depending on type of information, logging data is divided according to the following 6 levels inpython

1. **CRITICAL===>50**
   Represents a very serious problem that needs high attention

2. **ERROR ===>40**
   Represents a serious error

3. **WARNING ==>30**
   Represents a warning message, some caution needed. It is alert to the programmer.

4. **INFO==>20**
   Represents a message with some important information

5. **DEBUG ===>10**
   Represents a message with debugging information

6. **NOTSET==>0**
   Represents that level is not set

By default while executing Python program only WARNING and higher level messages will bedisplayed.

How to implement Logging:

To perform logging, first we required to create a file to store messages and we have to specifywhich level messages required to store.

We can do this by using basicConfig() function of logging module.

logging.basicConfig(filename='log.txt',level=logging.WARNING)

The above line will create a file log.txt and we can store either WARNING level or higher level messages to that file.

After creating log file, we can write messages to that file by using the following

methodslogging.debug(message)
logging.info(message)
logging.warning(message)
logging.error(message)
logging.critical(message)

Q. Write a Python Program to create a log file and write WARNING and Higher level messages?

```python
1)  import logging
2)  logging.basicConfig(filename='log.txt',level=logging.WARNING)
3)  print('Logging Demo')
4)  logging.debug('Debug Information')
5)  logging.info('info Information')
6)  logging.warning('warning Information')
7)  logging.error('error Information')
8)  logging.critical('critical Information')
```

log.txt:
WARNING:root:warning Information
ERROR:root:error Information
CRITICAL:root:critical Information

Note:
In the above program only WARNING and higher level messages will be written to the log file. Ifwe set level as DEBUG then all messages will be written to the log file.

test.py:

```python
1)  import logging
2)  logging.basicConfig(filename='log.txt',level=logging.DEBUG)
3)  print('Logging Demo')
4)  logging.debug('Debug Information')
5)  logging.info('info Information')
6)  logging.warning('warning Information')
```

```
7)  logging.error('error Information')
8)  logging.critical('critical Information')
```

log.txt:
DEBUG:root:Debug Information
INFO:root:info Information
WARNING:root:warning Information
ERROR:root:error Information
CRITICAL:root:critical Information

How to configure log file in over writing mode:

In the above program by default data will be appended to the log file.i.e append is the default mode. Instead of appending if we want to over write data then we have to use filemode property.

logging.basicConfig(filename='log786.txt',level=logging.WARNI
NG) meant for appending

logging.basicConfig(filename='log786.txt',level=logging.WARNING,filemode='a')
explicitly we are specifying appending.

logging.basicConfig(filename='log786.txt',level=logging.WARNING,filemode='w'
) meant for over writing of previous data.

Note:

logging.basicConfig(filename='log.txt',level=logging.DEBUG)

If we are not specifying level then the default level is WARNING(30)

If we are not specifying file name then the messages will be printed to the console.

test.py:

```
1)  import logging
2)  logging.basicConfig()
3)  print('Logging Demo')
4)  logging.debug('Debug Information')
5)  logging.info('info Information')
6)  logging.warning('warning Information')
7)  logging.error('error Information')
8)  logging.critical('critical Information')
```

D:\durgaclasses>py
test.pyLogging Demo
ARNING:root:warning Information
ERROR:root:error Information
CRITICAL:root:critical Information

How to Format log messages:

By using format keyword argument, we can format messages.

1. To display only level name:

   logging.basicConfig(format='%(levelname)s')

Output:
WARNIN
G
ERROR
CRITICA
L

2. To display levelname and message:

logging.basicConfig(format='%(levelname)s:%(message)s')

Output:
WARNING:warning
InformationERROR:error
Information
CRITICAL:critical
Information

How to add timestamp in the log messages:

logging.basicConfig(format='%(asctime)s:%(levelname)s:%(message)s')

Output:
2018-06-15 11:50:08,325:WARNING:warning Information
2018-06-15 11:50:08,372:ERROR:error Information
2018-06-15 11:50:08,372:CRITICAL:critical Information

How to change date and time format:

We have to use special keyword argument: datefmt

logging.basicConfig(format='%(asctime)s:%(levelname)s:%(message)s', datefmt='%d/%m/%Y %I:%M:%S %p')

datefmt='%d/%m/%Y %I:%M:%S %p' ===>case is important

Output:
5/06/2018 12:04:31 PM:WARNING:warning
Information15/06/2018 12:04:31 PM:ERROR:error
Information 15/06/2018 12:04:31
PM:CRITICAL:critical Information

Note:
%I--->means 12 Hours time scale
%H--->means 24 Hours time scale

Eg:
logging.basicConfig(format='%(asctime)s:%(levelname)s:%(message)s', datefmt='%d/%m/%Y %H:%M:%S')

Output:
15/06/2018 12:06:28:WARNING:warning Information
15/06/2018 12:06:28:ERROR:error Information
15/06/2018 12:06:28:CRITICAL:critical Information

https://docs.python.org/3/library/logging.html#logrecord-attributes

https://docs.python.org/3/library/time.html#time.strftime

How to write Python program exceptions to the log file:

By using the following function we can write exception information to the log file.

`logging.exception(msg)`

Q. Python Program to write exception information to the log file:

```
1)  import logging
2) logging.basicConfig(filename='mylog.txt',level=logging.INFO,format='%(asctime)s:%(levelname)s:%(message)s',datefmt='%d/%m/%Y  %I:%M:%S %p')
3)  logging.info('A new Request Came')
4)  try:
5)      x=int(input('Enter First Number:'))
6)      y=int(input('Enter Second Number:'))
7)      print('The Result:',x/y)
8)
9)  except ZeroDivisionError as msg:
10)     print('cannot divide with zero')
11)     logging.exception(msg)
12)
13) except ValueError as msg:
14)     print('Please provide int values only')
15)     logging.exception(msg)
16)
17) logging.info('Request Processing Completed')
```

D:\durgaclasses>py
test.pyEnter First
Number:10 Enter Second
Number:2 The Result: 5.0

D:\durgaclasses>py
test.pyEnter First
Number:20 Enter Second
Number:2 The Result:
10.0

D:\durgaclasses>py
test.pyEnter First
Number:10 Enter Second
Number:0 cannot divide
with zero

D:\durgaclasses>py test.py
Enter First Number:ten
Please provide int values
only

mylog.txt:

Problems with root logger:
If we are not defining our own logger,then bydefault root logger will be considered.
Once we perform basic configuration to root logger then the configurations are fixed and
wecannot change.

Demo Application:

student.py:

```
1) import logging
2) logging.basicConfig(filename='student.log',level=logging.INFO)
3) logging.info('info message from student module')
```

test.py:

```
1) import logging
2) import student
3) logging.basicConfig(filename='test.log',level=logging.DEBUG)
4) logging.debug('debug message from test module')
```

student.log:
INFO:root:info message from student module

In the above application the configurations performed in test module won't be reflected,b'z rootlogger is already configured in student module.

Need of Our own customized logger:

The problems with root logger are:

1. Once we set basic configuration then that configuration is final and we cannot change

2. It will always work for only one handler at a time, either console or file, but not bothsimultaneously

3. It is not possible to configure logger with different configurations at different levels

4. We cannot specify multiple log files for multiple modules/classes/methods.

To overcome these problems we should go for our own customized loggers

Advanced logging Module Features: Logger:

Logger is more advanced than basic logging.
It is highly recommended to use and it provides several extra features.

Steps for Advanced Logging:

1. Creation of Logger object and set log level

```
logger =
logging.getLogger('demologger')
logger.setLevel(logging.INFO)
```

2. Creation of Handler object and set log level
There are several types of Handlers like StreamHandler, FileHandler etc

```
consoleHandler =
logging.StreamHandler()
consoleHandler.setLevel(logging.INFO)
```

Note: If we use StreamHandler then log messages will be printed to console

3. Creation of Formatter object

```
formatter = logging.Formatter('%(asctime)s - %(name)s - %(levelname)s:
%(message)s',datefmt='%d/%m/%Y %I:%M:%S %p')
```

4. Add Formatter to Handler
```
consoleHandler.setFormatter(formatter
)
```

5. Add Handler to Logger
```
logger.addHandler(consoleHandle
r)
```

6. Write messages by using logger object and the following methods

```
logger.debug('debug message')
logger.info('info message')
logger.warn('warn message')
logger.error('error message')
logger.critical('critical
message')
```

Note: Bydefault logger will set to WARNING level. But we can set our own level based on our requirement.

```
logger =
logging.getLogger('demologger')
logger.setLevel(logging.INFO)
```

logger log level by default available to console and file handlers. If we are not satisfied with loggerlevel, then we can set log level explicitly at console level and file levels.

```
consoleHandler = logging.StreamHandler()
consoleHandler.setLevel(logging.WARNING)
```

```
fileHandler=logging.FileHandler('abc.log',mode='a')
fileHandler.setLevel(logging.ERROR)
```

Note:

console and file log levels should be supported by logger. i.e logger log level should be lower than console and file levels. Otherwise only logger log level will be considered.

Eg:
logger==>DEBUG console===>INFO------ >Valid and INFO will be considered
logger==>INFO console===>DEBUG ----- >Invalid and only INFO will be considered to the console.

Demo Program for Console Handler:

```python
1)  import logging
2)  class LoggerDemoConsole:
3)
4)      def testLog(self):
5)          logger = logging.getLogger('demologger')
6)          logger.setLevel(logging.INFO)
7)
8)          consoleHandler = logging.StreamHandler()
9)          consoleHandler.setLevel(logging.INFO)
10)
11)         formatter = logging.Formatter('%(asctime)s - %(name)s - %(levelname)s: %(message)s',
12)             datefmt='%m/%d/%Y %I:%M:%S %p')
13)
14)         consoleHandler.setFormatter(formatter)
15)         logger.addHandler(consoleHandler)
16)
17)         logger.debug('debug message')
18)         logger.info('info message')
19)         logger.warn('warn message')
20)         logger.error('error message')
21)         logger.critical('critical message')
22)
23) demo = LoggerDemoConsole()
24) demo.testLog()
```

D:\durgaclasses>py loggingdemo3.py
06/18/2018 12:14:15 PM - demologger - INFO: info message
06/18/2018 12:14:15 PM - demologger - WARNING: warn
message06/18/2018 12:14:15 PM - demologger - ERROR: error
message 06/18/2018 12:14:15 PM - demologger - CRITICAL:
critical message

Note:

If we want to use class name as logger name then we have to create logger object as follows

logger = logging.getLogger(LoggerDemoConsole.__name__

)In this case output is:

D:\durgaclasses>py loggingdemo3.py
06/18/2018 12:21:00 PM - LoggerDemoConsole - INFO: info message
06/18/2018 12:21:00 PM - LoggerDemoConsole - WARNING: warn
message06/18/2018 12:21:00 PM - LoggerDemoConsole - ERROR: error
message 06/18/2018 12:21:00 PM - LoggerDemoConsole - CRITICAL:
critical message

Demo Program for File Handler:

```python
1)  import logging
2)  class LoggerDemoConsole:
3)
4)      def testLog(self):
5)          logger = logging.getLogger('demologger')
6)          logger.setLevel(logging.INFO)
7)
8)          fileHandler = logging.FileHandler('abc.log',mode='a')
9)          fileHandler.setLevel(logging.INFO)
10)
11)         formatter = logging.Formatter('%(asctime)s - %(name)s -
    %(levelname)s: %(message)s',
12)             datefmt='%m/%d/%Y %I:%M:%S %p')
13)
14)         fileHandler.setFormatter(formatter)
15)         logger.addHandler(fileHandler)
16)
17)         logger.debug('debug message')
18)         logger.info('info message')
19)         logger.warn('warn message')
20)         logger.error('error message')
21)         logger.critical('critical message')
22)
23) demo = LoggerDemoConsole()
24) demo.testLog()
```

abc.log:
07/05/2018 08:58:04 AM - demologger - INFO: info message
07/05/2018 08:58:04 AM - demologger - WARNING: warn
message07/05/2018 08:58:04 AM - demologger - ERROR: error
message 07/05/2018 08:58:04 AM - demologger - CRITICAL:
critical message

Logger with Configuration File:

In the above program, everything we hard coded in the python script. It is not a good programming practice. We will configure all the required things inside a configuration file and wecan use this file directly in our program.

```
logging.config.fileConfig('logging.conf')
logger = logging.getLogger(LoggerDemoConf.__name__)
```

Note: **The extension of the file need not be conf. We can use any extension like txt or durga etc**

logging.conf:

```
[loggers]
keys=root,LoggerDemoConf

[handlers]
keys=fileHandle
r

[formatters]
keys=simpleFormatter

[logger_root]
level=DEBUG
handlers=fileHandle
r

[logger_LoggerDemoConf
]level=DEBUG
handlers=fileHandler
qualname=demoLogger

[handler_fileHandler]
class=FileHandler
level=DEBUG
formatter=simpleFormatte
rargs=('test.log', 'w')

[formatter_simpleFormatter]
format=%(asctime)s - %(name)s - %(levelname)s -
%(message)sdatefmt=%m/%d/%Y %I:%M:%S %p
```

test.py:

```python
1)  import logging
2)  import logging.config
3)  class LoggerDemoConf():
4)
5)    def testLog(self):
6)      logging.config.fileConfig('logging.conf')
7)      logger = logging.getLogger(LoggerDemoConf.__name__)
8)
9)      logger.debug('debug message')
10)     logger.info('info message')
11)     logger.warn('warn message')
12)     logger.error('error message')
13)     logger.critical('critical message')
14)
15) demo = LoggerDemoConf()
16) demo.testLog()
```

test.log:
06/18/2018 12:40:05 PM - LoggerDemoConf - DEBUG - debug
message 06/18/2018 12:40:05 PM - LoggerDemoConf - INFO - info
message 06/18/2018 12:40:05 PM - LoggerDemoConf - WARNING -
warn message06/18/2018 12:40:05 PM - LoggerDemoConf - ERROR -
error message 06/18/2018 12:40:05 PM - LoggerDemoConf -
CRITICAL - critical message

Case-1: To set log level as INFO:
[handler_fileHandler]
class=FileHandler
level=INFO
formatter=simpleFormatte
rargs=('test.log', 'w')

Case-2: To set Append Mode:

[handler_fileHandler]
class=FileHandler
level=INFO
formatter=simpleFormatte
rargs=('test.log', 'a')

Creation of Custom Logger:

customlogger.py:

```python
1)  import logging
2)  import inspect
3)  def getCustomLogger(level):
4)        # Get Name of class/method from where this method called
5)      loggername=inspect.stack()[1][3]
6)      logger=logging.getLogger(loggername)
7)      logger.setLevel(level)
8)
9)      fileHandler=logging.FileHandler('abc.log',mode='a')
10)     fileHandler.setLevel(level)
11)
12)     formatter = logging.Formatter('%(asctime)s - %(name)s - %(levelname)s: %(message)s',datefmt='%m/%d/%Y %I:%M:%S %p')
13)     fileHandler.setFormatter(formatter)
14)     logger.addHandler(fileHandler)
15)
16)     return logger
```

test.py:

```python
1)  import logging
2)  from customlogger import getCustomLogger
3)  class LoggingDemo:
4)      def m1(self):
5)          logger=getCustomLogger(logging.DEBUG)
6)          logger.debug('m1:debug message')
7)          logger.info('m1:info message')
8)          logger.warn('m1:warn message')
9)          logger.error('m1:error message')
10)         logger.critical('m1:critical message')
11)     def m2(self):
12)         logger=getCustomLogger(logging.WARNING)
13)         logger.debug('m2:debug message')
14)         logger.info('m2:info message')
15)         logger.warn('m2:warn message')
16)         logger.error('m2:error message')
17)         logger.critical('m2:critical message')
18)     def m3(self):
19)         logger=getCustomLogger(logging.ERROR)
20)         logger.debug('m3:debug message')
21)         logger.info('m3:info message')
22)         logger.warn('m3:warn message')
23)         logger.error('m3:error message')
24)         logger.critical('m3:critical message')
25)
26) l=LoggingDemo()
27) print('Custom Logger Demo')
28) l.m1()
29) l.m2()
30) l.m3()
```

abc.log:

06/19/2018 12:17:19 PM - m1 - DEBUG: m1:debug message
06/19/2018 12:17:19 PM - m1 - INFO: m1:info message

How to create seperate log file Based on Caller:

```python
1)  import logging
2)  import inspect
3)  def getCustomLogger(level):
4)      loggername=inspect.stack()[1][3]
5)      logger=logging.getLogger(loggername)
6)      logger.setLevel(level)
7)
8)      fileHandler=logging.FileHandler('{}.log'.format(loggername),mode='a')
9)      fileHandler.setLevel(level)
10)
11)     formatter = logging.Formatter('%(asctime)s - %(name)s -
        %(levelname)s: %(message)s',datefmt='%m/%d/%Y %I:%M:%S %p')
12)     fileHandler.setFormatter(formatter)
13)     logger.addHandler(fileHandler)
14)
15)     return logger
```

test.py:

#Same as previous

ss

```python
1)  import logging
2)  from customlogger import getCustomLogger
3)  class LoggingDemo:
4)      def m1(self):
5)          logger=getCustomLogger(logging.DEBUG)
6)          logger.debug('m1:debug message')
7)          logger.info('m1:info message')
8)          logger.warn('m1:warn message')
9)          logger.error('m1:error message')
10)         logger.critical('m1:critical message')
11)     def m2(self):
12)         logger=getCustomLogger(logging.WARNING)
13)         logger.debug('m2:debug message')
14)         logger.info('m2:info message')
15)         logger.warn('m2:warn message')
16)         logger.error('m2:error message')
17)         logger.critical('m2:critical message')
18)     def m3(self):
19)         logger=getCustomLogger(logging.ERROR)
20)         logger.debug('m3:debug message')
21)         logger.info('m3:info message')
22)         logger.warn('m3:warn message')
23)         logger.error('m3:error message')
24)         logger.critical('m3:critical message')
25)
```

```
26) l=LoggingDemo()
27) print('Logging Demo with Seperate Log File')
28) l.m1()
29) l.m2()
30) l.m3()
```

m1.log:
06/19/2018 12:26:04 PM - m1 - DEBUG: m1:debug message
06/19/2018 12:26:04 PM - m1 - INFO: m1:info message
06/19/2018 12:26:04 PM - m1 - WARNING: m1:warn
message06/19/2018 12:26:04 PM - m1 - ERROR: m1:error

06/19/2018 12:26:04 PM - m3 - CRITICAL: m3:critical message

Advantages of customized logger:

1. We can reuse same customlogger code where ever logger required.
2. For every caller we can able to create a seperate log fileFor different handlers we can set different log levels.

Another Example for Custom Handler:

customlogger.py:

```
1)  import logging
2) import inspect
3) def getCustomLogger(level):
4)     loggername=inspect.stack()[1][3]
5)
6)     logger=logging.getLogger(loggername)
7)     logger.setLevel(level)
8)     fileHandler=logging.FileHandler('test.log',mode='a')
9)     fileHandler.setLevel(level)
10)    formatter=logging.Formatter('%(asctime)s - %(name)s -
       %(levelname)s: %(message)s',datefmt='%m/%d/%Y %I:%M:%S %p')
11)    fileHandler.setFormatter(formatter)
12)    logger.addHandler(fileHandler)
13)    return logger
```

test.py:

```python
1)  import logging
2)  from customlogger import getCustomLogger
3)  class Test:
4)      def logtest(self):
5)          logger=getCustomLogger(logging.DEBUG)
6)          logger.debug('debug  message')
7)          logger.info('info  message')
8)          logger.warning('warning  message')
9)          logger.error('error  message')
10)         logger.critical('critical message')
11) t=Test()
12) t.logtest()
```

student.py:

```python
1)  import logging
2)  from customlogger import getCustomLogger
3)  def studentfunction():
4)      logger=getCustomLogger(logging.ERROR)
5)      logger.debug('debug  message')
6)      logger.info('info  message')
7)      logger.warning('warning  message')
8)      logger.error('error  message')
9)      logger.critical('critical message')
10) studentfunction()
```

Note: we can disable a partcular level of logging as follows:
logging.disable(logging.CRITICAL)
